Nature

A WEEKLY

ILLUSTRATED JOURNAL OF SCIENCE

VOLUME LXXII

MAY to OCTOBER, 1905

*"To the solid ground
Of Nature trusts the mind which builds for aye."*—WORDSWORTH

London
MACMILLAN AND CO., LIMITED
NEW YORK: THE MACMILLAN COMPANY

INDEX.

ABBOT (BRIG.-GENERAL HENRY L.), Problems of the Panama Canal, 394
Abderhalden (Emil), Recent Advances in the Chemistry of Albumin, 437
Abdominal Diseases, Clinical and Pathological Observations on Acute, E. M. Corner, 122
Aberration, the Constant of, Prof. Doolittle, 592
Aboriginal India, 105
Aboriginal Methods of determining the Seasons, William E. Rolston, 176
Abraham (Henri), Electrolytic Production of Very Fine Wires, 143; Recueil d'Expérience élémentaires de Physique, 172
Absence of Vibration in a Turbine Steamship, Prof. David Todd, 603
Absorption Spectra, Prof. H. Kayser, 627
Absorption Spectrum of Benzene in the Ultra-violet Region, on the, Dr. E. C. C. Baly and Prof. J. Norman Collie, F.R.S., 239, 630; Prof. W. N. Hartley, F.R.S., 557; Ultra-violet Absorption Spectra, the Phenols, E. C. C. Baly and E. K. Ewbank, 239
Academic Side of Technical Training, Dr. Alex. B. W. Kennedy, F.R.S., 256
Academy of the Lincei, Prize Awards, 461
Acoustics: Propagation of Musical Sounds in a Tube of 3 Metres Diameter, J. Violle and Th. Vautier, 95; the Amplitude of the Minimum Audible Impulsive Sound, Dr. P. E. Shaw, 503; Can Fish Hear? Dr. O. Körner, 638
Acquired Characters, the Inheritance of, W. Woods Smyth, 152
Adams (John), Effect of Very Low Temperature on Moist Seeds, 143
Adams (Prof.), the Orbit of ζ Tauri, 592
Aërolite Falls, Periodicity of, W. H. S. Monck, 230
Aëronautics: Atmospheric Electricity observed from Balloons, George C. Simpson, 92; International Aëronautical Committee's Ascents in January to April, 229; the Exploration of the Atmosphere above the Atlantic, A. Lawrence Rotch, 244; Projects of Artificial Flight, Arnold Samuelson, 329; Dr. Federico Sacco, 329; "Hélicoptère Aéroplane" of H. and A. Dufaux, Réné de Saussure, 329; Experiments with the Langley Aërodrome, Dr. S. P. Langley, 645
Africa: an Introduction to the Geology of Cape Colony, A. W. Rogers, Prof. Grenville A. J. Cole, 35; the Geology of South Africa, F. H. Hatch and G. S. Corstorphine, 346; Meeting of the British Association in South Africa, 59 (*see* British Association); the Masai, their Language and Folklore, A. C. Hollis, Sir H. H. Johnston, G.C.M.G., K.C.B., 83; Antelopes, Heuglin's "Giant Eland," A. L. Butler, 133; Ticks Concerned in the Dissemination of Disease in Man, Tick Fever in Congo Free State, R. Newstead, 354; Guinea Worm and its Hosts, Dr. Graham, 354; a Gigantic Gorilla, Prof. E. T. Hamy, 434; the Magic Origin of Moorish Designs, Dr. Westermarck, 435; Death and Obituary Notice of M. de Brazza, 515; New Gladiolus from Victoria Falls, 539; Science in South Africa, a Handbook and Review, 628
Agassiz (Prof. Alexander), Influence of the Humboldt Current on the Marine Life West of Callao, 17
Agriculture: Calcium Nitrate in Agriculture, E. S. Bellenoux, 47; Effect of Plant Growth and of Manures upon the Soil, A. D. Hall and N. H. J. Miller, 94; Agricultural Notes, 138; Phosphatic Fertilisers on Limed and on Unlimed Land, Mr. Nagaoka, 138; Work Done at the Rothamsted Experimental Station for the year ending March 31, A. D. Hall, 138; Sugar Cane Experiments in the Leeward Islands, Dr. F. Watts, 157; Determination of Sulphuric Acid in Soils, J. Howard Graham, 205; Ripening is due to Moulds and Bacteria in Camembert Type of Soft Cheese, 229; "Brusca," a Disease of the Olive, Prof. Cuboni, 276; Diseases of Citrous Plants and Fruits caused by the Fungus *Colletotrichum gloeosporioides*, P. H. Rolfs, 277; the State and Agriculture in Hungary, Dr. Ignatius Darányi, 291; British Fruit Growing, 297; Alfred O. Walker, 342; Spencer Pickering, F.R.S., 396; Recent Publications in Agricultural Science, 324; Concimi, Mangimi, Sementi, &c., Commercio, frodi, e repressione delle frodi, Specialmente in Italia, Italo Giglioli, 324; Field Operations of the Bureau of Soils, 1903, 325; Science and Practice of Agriculture, Farmer's Handbook, T. Jamieson, 325; the Seeding of Pastures, A. N. M'Alpine, 328; Cultivation of Oranges in Dominica, H. Hesketh Bell, 328; the Banana Industry in Costa Rica, 328; the Woburn Experimental Fruit Farm, Prof. T. H. Middleton, 461; Insect Pests of Field and Garden Crops, Prof. Theobald, 539; Leaf-hoppers and their Enemies, R. C. L. Perkins, 539; Indigo Planting and Synthetic Indigo, 637; Birds in the Field and Garden, 638; Manurial Experiments with Cacao in Dominica, West Indies, 639; Recent Developments in Agricultural Science, A. D. Hall, 642; Chemical Survey of the Soils of Cape Colony, 642
Aitken (John), Evaporation of Musk and other Substances, 391
Albrecht (Prof. T.), Variations of Latitudes, 110; Jupiter's Sixth and Seventh Satellites, 352; Observations of Jupiter's Seventh Satellite, 424
Albumin, Recent Advances in the Chemistry of, Emil Abderhalden, 437
Alchemical Equipment in the Eleventh Century A.D., H. E. Stapleton and R. F. Azo, 452
Alcohol, Duty-free, Dr. F. Mollwo Perkin, 344
Aldrich (J. M.), a Catalogue of North American Diptera or Two-winged Flies, 317
Alessandri (Dr.), the Monte Rosa Observatory, 565
Alexander (A. D.), Explosions of Mixtures of Coal-gas and Air in a Closed Vessel, 311
Algebra: Modern Algebra, A. B. Basset, F.R.S., 30; a First Algebra, W. M. Baker and A. A. Bourne, 393;

Algebraical Grounding, D. E. Shorto, 393; Examples in Algebra, Charles M. Clay, 393
Algeria: Monographie des Cynipides d'Europe et d'Algérie, l'Abbé J. J. Kieffer, 455
Algiers, New Observatory in, Lucien Libert, 207
Allen (E. T.), the Isomorphism and Thermal Properties of the Felspars, 258; the Scorification Assay for Gold Telluride Ores, 493
Allen (Dr. F. J.), the Critical Temperature and Pressure of Living Substances, 7
Alpheraky (Sergius), the Geese of Europe and Asia, 266
Alternating Currents, A. Russell, Maurice Solomon, 99
Alvarez (Eugenio Piñerúa), New Reagent for Potassium, 47; a New Osmium Compound, 72; a Reaction of Rhodium, 96
Amann (M.), the Rings of Saturn, 388
America: Astronomical Society of America, 19; Biologia Centrali-Americana, Aves, Osbert Salvin, F.R.S., and Frederick Ducane Godman, F.R.S., 49; University of Pennsylvania, Transactions of the Department of Archæology, Free Museum of Science and Art, H. R. Hall, 98; Manual of the Trees of North America (exclusive of Mexico), C. S. Sargent, 197; a Catalogue of North American Diptera or Two-winged Flies, J. M. Aldrich, 317; American Research in Asia, Prof. Grenville A. J. Cole, 366; the American Thoroughbred, C. E. Trevathan, 395
Anatomy: First International Congress of Anatomists, 400; Importance of Selecting Generalised Species for Anatomical Demonstrations, Dr. H. W. Rand, 302; Coral Anatomy and development, Dr. J. E. Duerden, 185
Ancient Antarctica, Captain F. W. Hutton, F.R.S., 244
Andersen (K.), Some Species of Bats of the Genus Rhinolophus, 119
Anderson (E. L.), Riding and Driving, 197
Anderson (Prof. R. J.), Physical Deterioration, 331
Andoyer (M.), Further Results obtained by the French Eclipse Expeditions, 567
Andrews (Leonard), Electricity Control, a Treatise on Switch-gear Systems of Electric Transmission, 99
Andrews (Thomas, F.R.S.), Wear of Steel Rails on Bridges, 573
Angler's Hours, an, H. T. Sherringham, 220
Anglo-Saxons, Latins et, Races supérieures et Races inférieures, Prof. N. Colajanni, 533
Animals: Animal Photography, 54; Animals I Have Known, A. H. Beavan, 125; the Preservation of Native Plants and Animals, Prof. W. B. Benham, 534
Annandale (Dr. N.), Occurrence of the Fresh-water Worm Chætogaster in India, 24; Four New Barnacles from the Neighbourhood of Java, 360; the Færöes and Iceland, Studies in Island Life, 506
Anomalous Dispersion and "Flocculi," Prof. Julius, 19
Anopheles Mosquitoes of India, a Monograph of the, S. P. James and Dr. W. G. Liston, Dr. J. W. W. Stephens, 73
Antarctica: Scientific Results of the National Antarctic Expedition, 57; Antarctic Expedition, Dr. J. Charcot, 207; Ancient Antarctica, Captain F. W. Hutton, F.R.S., 244
Anthropology: the Probable Racial Constituents of the Portuguese, A. da Costa Ferreira, 87; a Penitential Rite of the Ancient Mexicans, Drawing Blood, Mrs. Zelia Nuttall, 88; Anthropological Institute, 118; I Nuovi Indirizzi e le Promesse della Odierna Antropologia, Fabio Frassetto, 173; the Magic Origin of Moorish Designs, Dr. Westermarck, 435; Les Six Races composant la Population actuelle de l'Europe, Dr. Deniker, 464; Remains of Neolithic Buildings in Scandinavia, H. Schetelig, 515; Latins et Anglo-Saxons, Races supérieures et Races inférieures, Prof. N. Colajanni, 533; Machine-made Eoliths, M. Boule, 538; on the Origin of Eoliths, Marcellin Boule, 635; Dr. Hugo Obermaier, 636; Greek Grotesque Figures as Charms against the Evil Eye, A. J. B. Wace, 560; Decorative Objects Worn by the Natives of Borneo, R. Shelford, 638
Anthropometric Survey, Physical Deterioration, being the Report of Papers and Discussions at the Cambridge Meeting of the British Association, 1904, on the Alleged Physical Deterioration of the People and the Utility of an, 152
Anti-typhoid Inoculation, a Short Treatise on, Dr. A. E. Wright, 122
Antlitz der Erde, das, Prof. Eduard Suess, 193
Appendix Vermiformis, the Surgery of the Diseases of the, and their Complications, W. H. Battle and E. M. Corner, 122
Appleyard (Rollo), Contact with Dielectrics, 215
Aquilæ, Nova, No. 2, Prof. Max Wolf, 494, 611; Dr. P. Guthnick, 494, 611; Prof. Hartwig, 518; Mrs. Fleming, 542; Prof. Pickering, 640
Arachnida: on Two Orders of Arachnida, Opiliones, especially the Suborder Cyphophthalmi, and Ricinulei, namely, the Family Cryptostemmatoidæ, Dr. H. J. Hansen and Dr. W. Sörensen, R. I. Pocock, 577; Palaeozoische Arachniden, Prof. Dr. Anton Fritsch, R. I. Pocock, 577
Arber (E. A. N.), Seed-bearing Habit in the Lyginodendreæ, 166
Archæology: Relation between Stonehenge, Old Sarum, and Grovely Castle, Colonel Johnston, 16; Notes on Stonehenge, Sir Norman Lockyer, K.C.B., F.R.S., 32, 246, 270; Prehistoric Graves and Dwelling Places near Breslau, 63; the Evolution of Engraving in the Stone Age, Ed. Piette, 81; University of Pennsylvania, Transactions of the Department of Archæology, Free Museum of Science and Art, H. R. Hall, 98; an Inverted Slab in a Cromlech, Edward Greenly, 152; Results obtained in Egypt by Prof. Flinders Petrie, 228; British Archæology and Philistinism, Worthington G. Smith, 294; Money-boxes in the Form of Mammæ, F. Rosen, 386; Forty Years' Researches in British and Saxon Burial Mounds of East Yorkshire, J. R. Mortimer, 398; Death of Prof. Jules Oppert, 421; Obituary Notice, 432; the Annual of the British School at Athens, H. R. Hall, 558; Dr. Arthur Evans's Work at Knossos, 558; Excavations at Palaîkastro, Messrs. Dawkins and Currelly, 559; the "Aryanism" of the Minoans, R. S. Conway, 566
Architecture, Naval: Institution of Naval Architects, 303; Experiments with Models of Constant Length and Form of Cross Section, but with Varying Breadths and Draughts, Lieut.-Colonel B. Rota, 303; Experiments upon the Effect of Water on Speed, Harold Yarrow, 303; Influence of the Depth of Water on Speed, W. W. Marriner, 303; Causes of Accidents to Submarine Boats, Captain R. H. Bacon, 306
Arctica: the Norwegian North Polar Expedition, 1893–1896, Scientific Results, 265; Commander Peary's Expedition to North Pole, 274; Return of the Ziegler North Polar Expedition, A. Fiala, 422; New Island discovered, Terre de France, Lieut. Bergendahl, 461; Death and Obituary Notice of Captain J. Wiggins, 515
Area-scale, Radial, R. W. K. Edwards, 150
Argentine Republic, Ben Nevis Observatory and the, William S. Bruce, 485
Arithmetic: a Text-book of Chemical Arithmetic, Horace L. Wells, 556; Examples in Arithmetic, C. O. Tuckey, 580; the Primary Arithmetic, 580
Arloing (Prof.), the Infection of Man by Bovine Tubercle Bacilli, 582
Armstrong (Dr. E. F.), the *Rôle* of Enzymes in Plant Economy, 642
Arnold (F.), Consciousness and its Object, 464
Arnold (Prof. J. O.), Thermal Transformations of Carbon Steels, 572
Arrhenius (Prof. Svante), the Electrical Charge of the Sun, 43
Arsonval (Prof. d'), Apparatus for Generation and Automatic Compression of Oxygen, 541
Artificial Diamonds, Dr. C. V. Burton, 307
Ascent of Sap in Trees, the Mechanics of the, Prof. J. Larmor, Sec.R.S., at Royal Society, 644
Ashworth (James), Outbursts of Gas and Coal at the Morrissey Collieries, British Columbia, 131
Asia: the Geese of Europe and Asia, Sergius Alpheraky, 266
Asiatic Society of Bengal, 24, 120, 360, 452
Asphalt Pavement, the Modern, Clifford Richardson, 316
Assaying, Notes on, and Metallurgical Laboratory Experiments, Prof. Richard W. Lodge, 340
Assheton (R.), Morphology of the Ungulate Placenta, 391

Assyriology: Death of Prof. Jules Oppert, 421; Obituary Notice of, 432
Asteroids: Occlo [475], an Interesting Asteroid, R. H. Frost, 330, 388; Variation of a Newly Discovered Asteroid, Dr. Palisa, 494; the Variable Asteroid 1905 Q.Y., Dr. Palisa, 518; Prof. Berberich, 518; Ephemeris of the Variable Asteroid (167) Urda, A. Berberich, 542
Astronomy: Recent Spectroheliograph Results, Dr. William J. S. Lockyer, 9; Phillip Fox, 183; Interpretation of Spectroheliograph Pictures, M. N. Donitch, 495; Prof. Hale and Mr. Ellerman, 495; Our Astronomical Column, 19, 43, 66, 89, 110, 135, 158, 183, 207, 230, 255, 279, 302, 330, 352, 388, 424, 436, 465, 494, 518, 542, 567, 591, 610, 639; Discovery of a Tenth Satellite to Saturn, 19, 135; Prof. W. H. Pickering, 19; Observations of the Satellites of Saturn and Uranus, Messrs. Frederick and Hammond, 230; the Rings of Saturn, MM. Amann and Rozet, 388; Light-variation of Saturn's Satellites, Dr. P. Guthnick, 611; Observations of Phœbe, R. H. Frost, 330; the Alleged Identity of Comets "Brooks 1889" and Lexell, Dr. Charles L. Poor, 19; Ancient Drawings of Celestial Phenomena, Dr. W. Lehmann, 19; Mount Wilson Observatory, Prof. Hale, 19; Anomalous Dispersion and "Flocculi," Prof. Julius, 19; Astronomical Society of America, 19; Astronomy for Amateurs, Camille Flammarion, 29; Notes on Stonehenge, Sir Norman Lockyer, K.C.B., F.R.S., 32, 246, 270; Death of Prof. Otto von Struve, 38; Obituary Notice of, 61; Ephemeris for Comet 1905*a*, M. Ebell, 43; Orbit of Comet 1905*a*, Miss Lamson, 66; Elliptical Elements for the Orbit of Comet 1905*a*, Prof. Banachiewicz, 207; A. Wedemayer, 207; Comets 1905 II (1904*e*) and 1904 I, Dr. Strömgren, 43; Herr Nijland and Herr van d. Bilt, 43; Observations of Jupiter, MM. Flammarion and Benoit, 43; a Suspected Sudden Change on Jupiter, Major Molesworth, 207; Observations of Jupiter's Great Red Spot, Stanley Williams, 330; Eye-estimates of the Transits of Jupiter's Spots, Rev. T. E. R. Phillips, 518; Provisional Elements for Jupiter's Sixth Satellite, Mr. Crommelin, 66; Brightness of Jupiter's Satellites, Prof. Wendell, 66; Prof. W. de Sitter, 207; Jupiter's Sixth and Seventh Satellites, Prof. Perrine, 135; Dr. Albrecht, 352; Dr. Frank E. Ross, 352; Observation of Jupiter's Seventh Satellite, Prof. Albrecht, 424; Observations of Jupiter's Satellites, Profs. A. A. Nijland and J. van d. Bilt, 567; the Electrical Charge of the Sun, Prof. Svante Arrhenius, 43; Memoria sobre el Eclipse Total de Sol del dia 30 de Agosto de 1905, D. Antonio Tarazona, 77; Mechanical Lantern Slide Illustrative of the Phenomenon of a Total Solar Eclipse, W. Shackleton, 91; Geodetic Measurements from Solar Eclipses, C. E. Stromeyer, 230; Proposed Observation of Mercury during the Solar Eclipse, Dr. G. Johnstone Stoney, F.R.S., 244; the French Eclipse Expeditions, 279; French Observations of the Total Solar Eclipse, Prof. Janssen, 518; M. Bigourdan, 518; M. Stephan and M. Trépied, 518; M. Bourget, 518; M. Nordmann, 518; M. Salet, 518; M. Moye, 518; Further Results obtained by the French Eclipse Expeditions, MM. Deslandres and Andoyer, 567; M. Salet, 591; Prof. Janssen, 639; E. Stephan, 640; M. Bigourdan's Eclipse Results, 610; Eclipse Shadow Bands, A. Lawrence Rotch, 307; Proposed Magnetic and Allied Observations during the Total Solar Eclipse on August 30, Dr. L. A. Bauer, 342; the Forthcoming Total Solar Eclipse, Dr. William J. S. Lockyer, 399; the Total Solar Eclipse, August 30, Dr. William J. S. Lockyer, 457; Observations of the Total Solar Eclipse in Tripoli, Barbary, Prof. David Todd, 484; Observations of the Electric Conditions of the Atmosphere during the Recent Solar Eclipse, Prof. F. Elster, Prof. H. Geitel and F. Harms, 490; the Solar Physics Observatory Eclipse Expedition, Dr. William J. S. Lockyer, 508; Influence of the Eclipse of August 30 on Plants, Ed. Bureau, 528; Observations of the Total Eclipse of the Sun at Guelma, Ch. Trépied, 576; Eclipse Predictions, J. Y. Buchanan, F.R.S., 603; Dr. A. M. W. Downing, F.R.S., 629; Eclipse Phenomena, Sir Oliver Lodge, F.R.S., 629; Observations of "D_3" in the Solar Spectrum, Dr. H. Kreusler, 66; Visibility of D_3 as a Dark Line in the Solar Spectrum, Prof. A. Fowler, 184; A. Buss, 184; Solar Changes and Weather, Dr. William J. S. Lockyer, 129, 175; A. B. M., 175; Solar and Terrestrial Changes, 249; Observations of Prominences on the Sun's Limb, Prof. Mascari, 158; the Solar Activity, 279; the Solar Activity, January–June, Prof. Mascari, 518; Dutch Observations of the Corona, Prof. Julius, 303; a Solar Outburst? Arthur Mee, 320; Cosmic Dust of Solar Origin, Prof. Schaeberle, 424; a Proposed New Method for determining the Solar Radiation, Prof. Ceraski, 437; the Figure of the Sun, C. Lane Poor, 567; Vegetation and the Sun-spot Period, Camille Flammarion, 303; Sun-spot Spectra, W. M. Mitchell, 330; Another Large Sun-spot, 610; the Recent Large Sun-spot, 639; Atmospheric Origin of "Shadow Bands," T. Zona, 611; the Problem of "Shadow-bands," Catharine O. Stevens, 631; a Spectrographic determination of the Solar Parallax, F. Küstner, 611; the International Union for Cooperation in Solar Research, 490; Variability of Minor Planet (15) Eunomia, Prof. Wendell, 43; Faintness of Planetary Nebulæ, J. E. Gore, 43; Variable Stars in the Small Magellanic Cloud, Miss Leavitt, 66; Observations and Light-curves of Several Variable Stars, Dr. L. Terkán, 66; Twelve Stars with Variable Radial Velocities, Prof. Wright and Dr. Palmer, 89; a Remarkable Variable Star, Prof. E. C. Pickering, 110; Variable Stars in the Clusters Messier 3 and 5, Prof. Bailey, 183; Winter Fireballs in 1905, Mr. Denning, 66; Newly discovered Nebulæ, Prof. Max Wolf, 89; the Bruce Telescope Reference Photographs, Prof. Pickering, 89; Comet 1904 II (1904*d*), M. Ebell, 89; Double "Canals" on Mars in 1903, Mr. Lowell, 89; Photographic Reality of the Martian Canals, Mr. Lowell, 135; Photographs of the Martian Canals, Mr. Lampland, 302; Mr. Lowell, 302; a Projection on Mars, Mr. Lowell, 279, the North Polar Snow-cap on Mars, 1904–5, Messrs. Lowell and Lampland, 303; the Formation of the Martian Snow-caps, Prof. W. H. Pickering, 255; the Formation of the New North Polar Cap on Mars, Mr. Lowell, 352; the Planet Mars, Mr. Wesley, 388; Mr. Denning, 388; Major Molesworth, 388; Water Vapour in the Martian Atmosphere, Mr. Lowell, 465; Mr. Slipher, 465; Catalogue of New Double Stars, Prof. Hussey, 90; Astronomical Occurrences in June, 110; in July, 207; in August, 302; in September, 436; in October, 542; Radial Velocities of Thirty-one Stars, Prof. Lord, 110; Magnitudes of Nova Persei and Nova Geminorum, Prof. A. A. Nijland, 110; Oxford University Observatory, Prof. Turner, 110; Variations of Latitude, Prof. T. Albrecht, 110; New Refraction Tables, Prof. Eichelberger, 110; the Motion of the Tail of Borrelly's Comet (1903 iv), Prof. Jaegermann, 135; Double Star Observations, J. A. Miller and Prof. W. A. Cogshall, 135; Stars with Spectra of the Orion Type, Prof. Pickering, 135; the Royal Observatory, Greenwich, 135; a Probable Nova in Ophiuchus, Mr. Fleming, 158; Miss Cannon, 158; Prof. Pickering, 158; Determination of Meteor Radiants, Mr. Denning, 158; Aboriginal Methods of determining the Seasons, William E. Rolston, 176; Stars with Peculiar Spectra, Mrs. Fleming, 183; Prof. Pickering, 183; West Hendon House Observatory, 184; Perturbations of the Bielid Meteors, Dr. A. M. W. Downing, F.R.S., 189; Royal Astronomical Society, 190; Determination of Heat Radiation from the Moon, Earl of Rosse, 190; Diurnal Variations of Nadir and Level of the Greenwich Transit Circle, Astronomer Royal, 190; Recent Positions of Eros, Mr. Manson, 207; Recent Observation of Eros, Prof. Millosevich, 256; New Observatory in Algiers, Lucien Libert, 207; Telescopic Work for Observers of Planets, W. F. Denning, 208; Monochromatic Photographs of the Orion Nebula, Prof. Hartmann, 230; Periodicity of Aërolite Falls, W. H. S. Monck, 230; the Reality of Supposed Changes on the Moon's Surface, M. Puiseux, 230; the Circumzenithal Apparatus, MM. Nušl and Frič, 230; Determination of Constant of Aberration by Observation of Three Stars Close to the Pole, H. Renan and W. Ebert, 239; the Constant of Aberration, Prof. Doolittle, 592; the Planet Uranus, W. F. Denning, 244; July and August Meteors, 255; Standard Time in Various Countries, Rear-Admiral Chester, 256; Harvard College Observatory Annual Report, Prof. E. C. Pickering, 256; Prof. Wendell, 256; Mrs. Fleming, 256; Prof. Frost,

256; Observations of Perseids, Robert Dole, 279; a Remarkable Meteor, Dr. G. Johnstone Stoney, 279; Visibility of the Dark Hemisphere of Venus, M. Hansky, 303; Determinations of Meteor Radiants, M. Eginitis, 303; Prof. A. A. Nijland, 303; Astronomischer Jahresbericht, Walter F. Wislicenus, 317; an Interesting Asteroid, Occlo [475], R. H. Frost, 330; the Minor Planet Occlo (475), R. H. Frost, 388; Periods of the Variable Stars S Sagittæ and Y Ophiuchi, M. Luizet, 330; Œuvres complètes de Christiaan Huygens, 362; Declinations of Certain North Polar Stars, Dr. Auwers, 388; Harriet Bigelow, 388; the Royal University Observatory of Vienna, 388; the Orbit of γ Coronæ Borealis, Mr. Doberck, 424; Atlas of Emission Spectra of most of the Elements, Drs. Hagenback and Konen, 426; Observations of Planets, Mr. Denning, 436; Proper Motions of the Hyades, Prof. Donner, Profs. Kapteyn and W. de Sitter, 436; Variation of Latitude, Messrs. Kimura and Nakano, 437; the Cape Observatory, 437; Discovery of a Nova, Mrs. Fleming, 465; Prof. Pickering, 465; Real Paths of Lyrid Meteors, Mr. Denning, 465; Observations of Satellites, Dr. C. W. Wirtz, 465; Handbuch der geographischen Ortbestimmung für Geographen und Forschungsreisende, Dr. Adolf Marcuse, 481; Variation of a Newly Discovered Asteroid, Dr. Palisa, 494; the Observatory of Paris, M. Lœwy, 495; Nova Aquilæ No. 2, Prof. Max Wolf, 494, 611; Dr. P. Guthnick, 494, 611; Prof. Hartwig, 518; Mrs. Fleming, 542; Prof. Pickering, 640; the Variable Asteroid 1905 Q.Y., Dr. Palisa, 518; Prof. Berberich, 518; Our Stellar Universe, a Road-book to the Stars, Thomas Edward Heath, 531; Our Stellar Universe (Six Stereograms of Sun and Stars), Thomas E. Heath, 531; Ephemeris of the Variable Asteroid (167) Urda, A. Berberich, 542; the Ultra-violet Chromospheric Spectrum, H. Deslandres, 542; International Union for Cooperation in Solar Research, 563; Bibliography of Halley, 567; a Lost Double Star, Prof. Doolittle, 567; Elements of Comet 1886 viii., E. Fagerholm, 567; Death of Rev. S. J. Johnson, 588; Cosmical Evolution, J. H. Jeans, 591; Visibility of Faint Stars at the Lowell Observatory, Mr. Lampland, 592; Mr. Lowell, 592; the Orbit of ζ Tauri, Profs. Frost and Adams, 592; the Natal Government Observatory, 592; Incandescence of Meteors, George A. Brown, 604; A. S. H., 604; Star with a Large Proper Motion, Miss Leavitt, 640; Observations of Perseids, August, 640; *see also* British Association

Section C (*Geology*)—Opening Address by Prof. H. A. Miers, M.A., D.Sc., F.R.S., President of the Section, 405
Section D (*Zoology*)—Opening Address by G. A. Boulenger, F.R.S., V.P.Z.S., President of the Section, the Distribution of African Fresh-water Fishes, 413
Section E (*Geography*)—Opening Address by Rear-Admiral Sir W. J. L. Wharton, K.C.B., F.R.S., President of the Section, 445
Section G (*Engineering*)—Opening Address by Colonel Sir C. Scott Moncrieff, K.C.S.I., K.C.M.G., R.E., LL.D., President of the Section, Irrigation, 465
Section H (*Anthropology*)—Opening Address by A. C. Haddon, Sc.D., F.R.S., President of the Section, 471
Section I (*Physiology*)—Opening Address by Colonel D. Bruce, M.B., F.R.S., C.B., President of the Section, the Advance in our Knowledge of the Causation and Methods of Prevention of Stock Diseases in South Africa during the Last Ten Years, 496
Section K (*Botany*)—Opening Address by Harold Wager, F.R.S., H.M.I., President of the Section, on Some Problems of Cell Structure and Physiology, 519
Section L (*Educational Science*)—Opening Address by Sir Richard C. Jebb, Litt.D., D.C.L., M.P., President of the Section, University Education and National Life, 545
British Association: Physical Deterioration, being the Report of Papers and Discussions at the Cambridge Meeting of the British Association, 1904, on the Alleged Physical Deterioration of the People and the Utility of an Anthropometric Survey, 152
British Bird Life, W. Percival Westell, 196
British Colonies, the Oxford Atlas of the, 293
British Fruit Growing, 297; Alfred O. Walker, 342; Spencer Pickering, F.R.S., 396
British Islands, a Handbook to a Collection of the Minerals of the, in the Museum of Practical Geology, F. W. Rudler, 76
British Islands, the Mythology of the, Charles Squire, 145
British Medical Association, the Meeting of the, 330, 354
British Moss-flora, the, Dr. R. Braithwaite, 425
British Museum, Guide to the Gallery of Birds in the, 28; Catalogue of the Lepidoptera Phalænæ in the British Museum, Sir George F. Hampson, Bart., 174
British Pharmaceutical Conference, Presidential Address at, Standardisation in Pharmacy, W. A. H. Naylor, 334
British and Saxon Burial Mounds of East Yorkshire, Forty Years' Researches in, J. R. Mortimer, 398
British School at Athens, the Annual of the, H. R. Hall, 558
British Science Guild, the, 585
British Slugs, the, Prof. T. D. A. Cockerell, 245
"Brooks 1889" and Lexell, the Alleged Identity of Comets, Dr. Charles L. Poor, 10
Broom (Dr. R.), the Age and Affinities of Tritylodon, 285
Brown (George A.), Incandescence of Meteors, 604
Brown (Dr. Horace T.), Researches on the Assimilatory Processes of Plants, 642
Brown (J. C.), Precise Method of Estimating the Organic Nitrogen in Potable Waters, 239
Browne (E. T.), Medusæ found in the Firth of Clyde, 191
Browne (Frank Balfour), Reports on Sea Fisheries, 138
Browne (Sir James Crichton, F.R.S.), the Prevention of Senility, 306
Bruce Telescope Reference Photographs, the, Prof. Pickering, 89
Bruce (Dr. A.), Distribution of the Nerve Cells in the Intermedio-lateral Tract of the Dorso-lumbar Region of the Human Spinal Cord, 191
Bruce (Colonel D., M.B., F.R.S., C.B.), Opening Address in Section I at the Meeting of the British Association in South Africa, the Advance in our Knowledge of the Causation and Methods of Prevention of Stock Diseases in South Africa during the Last Ten Years, 496
Bruce (William S.), Ben Nevis Observatory and the Argentine Republic, 485
Brühl (Prof. J. W.), Desmotropic Form of Substances of the Ethyl Acetoacetate Type, 141; the Development of Spectrochemistry, Lecture at the Royal Institution, 158
Bryan (Prof. G. H., F.R.S.), Fictitious Problems in Mathematics, 102, 175; Streifzüge an der Riviera, Eduard Strasburger, 171
"Bubbling" Method and Vapour Pressures, the, the Earl of Berkeley and E. G. J. Hartley, 222
Buchanan (J. Y., F.R.S.), Eclipse Predictions, 603
Bucherer (Dr. A. H.), Mathematische Einfuhrung in die Elektronentheorie, 170

Buckton (George Bowdler, F.R.S.), Death of, 537; Obituary Notice of, W. F. Kirby, 587
Building, Ferro-concrete, Ed. Noaillon, 213
Burch (Dr. George J., F.R.S.), Studien ueber Hautelektricität und Hautmagnetismus des Menschen, Dr. Erik Harnack, 602
Burdon (E. R.), Beiträge zur physiologischen Anatomie der Pilzgallen, Hermann Ritter von Guttenberg, 339
Bureau (Ed.), Influence of the Eclipse of August 30 on Plants, 528
Burial Mounds of East Yorkshire, Forty Years' Researches in British and Saxon, J. R. Mortimer, 398
Burke (John Butler), on the Spontaneous Action of Radioactive Bodies on Gelatin Media, 78; on the Spontaneous Action of Radium on Gelatin Media, 294
Burke (Mr.), the Origin of Life, 492
Burnside (Prof. W.), Conditions of Reducibility of any Group of Linear Substitutions, 190; Criteria for the Finiteness of Order of a Group of Linear Substitutions, 190
Burton (Dr. C. V.), the Hydrometer as a Seismometer, 269; Artificial Diamonds, 307
Burton (W.), Connection between Scientific Training and Industrial Development, 608
Busquet (Raymond), Précis d'Hydraulique—La Houille Blanche, 427
Buss (A.), Visibility of D_3 as a Dark Line in the Solar Spectrum, 184
Butler (A. L.), Antelopes, Heughlin's "Giant Eland," 133
Butler (W.), the Swingcam Camera Stand, 89
Butterfield (W. Ruskin), Protective Coloration of the Inside of the Mouth in Nestling Birds, 534
Butterflies: the Fauna of British India, including Ceylon and Burma, Lieut.-Colonel C. T. Bingham, 290
Butterflies, Moths and, Mary C. Dickerson, 76
Byrom (T. H.), the Physics and Chemistry of Mining, 557

Cacao, Manurial Experiments with, in Dominica, West Indies, 639
Cain (J. C.), Action of Water on Diazo-salts, 239; the Synthetic Dyestuffs and the Intermediate Products from which they are Derived, Supp. to October 19, vii
Calculus, Elements of the Differential and Integral, William Anthony Granville, Prof. George M. Minchin, F.R.S., 26; D. F. Campbell, 126
Calcutta: Asiatic Society of Bengal, 24, 120, 360, 452
Callendar (Prof. H. L.), a Bolometer for the Absolute Measurement of Radiation, 118
Calmette (M.), Transference of Infection in Ankylostomiasis through the Skin, 107
Calmette (Dr.), Specimens from Goats and Kids, 582
Calorimetry, Gas, 186
Cambage (R. H.), Eucalypts of the Blue Mountains, N.S.W., 312; the Native Flora of New South Wales, 312
Cambridge Natural History, the, 103
Cambridge Philosophical Society, 142, 166
Camera in the Fields, the, F. C. Snell, 153
Cameroons, on a New Species of Guenon from the, Dr. Henry O. Forbes, 630
Camichel (C.), Fluorescence, 336
Campbell (D. F.), the Elements of the Differential and Integral Calculus, 126
Campbell (Prof. E. D.), Copper, Cobalt, and Nickel in American Pig-irons, 573
Campbell (M. R.), the Coal and Lignites of the United States, Preliminary Report, 493–4
Campbell (N. R.), a Null Method of Measuring Small Ionisation, 142
Canada, Glacial Studies in, Dr. William H. Sherzer, Prof. Grenville A. J. Cole, 310
"Canals" on Mars in 1903, Double, Mr. Lowell, 89; *see* Astronomy
Cancer: the so-called "Cancer Bodies" (Ruffer's Bodies) of Malignant Tumours, C. Walker, 86; the Immunisation of Mice against Cancer, Dr. Clowes, 86; Resemblances between "Plimmer's Bodies" of Malignant Growths and Certain Normal Constituents of Reproductive Cells of Animals, Prof. J. Bretland Farmer, F.R.S., J. E. S. Moore and C. E. Walker, 164; the Present Position of the Cancer Problem, Prof. R. T. Hewlett, 295; X-Rays, their Employment in Cancer and other Diseases, Richard J. Cowen, 395
Cannon (Miss), a Probable Nova in Ophiuchus, 158
Cape Colony, an Introduction to the Geology of, A. W. Rogers, Prof. Grenville A. J. Cole, 35
Cape Observatory, the, 437
Carbutt (Sir Edward H.), Death and Obituary Notice of, 588
Carmichael (N. R.), Physical Experiments, 126
Carpenter (Dr. H. C. H.), High-speed Tool Steels under Varying Thermal Treatment, 60
Carson (C.), Interaction of Hydrogen Sulphide and Sulphur Dioxide, 71
Cash (Dr. J. Theodore, F.R.S.), Pharmacology of Indaconitine and Bikhaconitine, 551
Castle (Frank), Machine Construction and Drawing, 533
Caunt (G. W.), Geometrical Conics, 303
Cause and Prevention of Dust from Automobiles, W. R. Cooper, 485, 507; J. Vincent Elsden, 507
Celestial Phenomena, Ancient Drawings of, Dr. W. Lehmann, 10
Cell Structure and Physiology, on some Problems of, Opening Address in Section K at the Meeting of the British Association in South Africa, Harold Wager, F.R.S., H.M.I., 519
Celtic Pony, the, Dr. Francis H. A. Marshall, 558
Celts, the Literature of the, its History and Romance, Magnus Maclean, 145
Ceraski (Prof.), a Proposed New Method for Determining the Solar Radiation, 437
Cerebellum, the, its Relation to Spatial Orientation and Locomotion, Boyle Lecture at Oxford, Sir Victor Horsley, F.R.S., 389
Chablay (E.), Action of Metal Ammoniums on the Halogen Derivatives of Methane, 72; Action of the Metal Ammoniums on Alcohols, 96; Action of the Metal Ammoniums on the Polyatomic Alcohols, 119
Chagos Archipelago, the, the Percy Sladen Expedition in H.M.S. *Sealark*, J. Stanley Gardiner, 571
Chalk Masses in the Cliffs near Cromer, Prof. T. G. Bonney, F.R.S., 8
Challenger Society, 118, 203
Chamberlin (Thomas C.), Geology Processes and their Results, 289
Chanoz (M.), the Effect of Membranes in Liquid Chains, 312; Experimental Researches on the Effect of Membranes in Liquid Chains, 336
Chapman (D. L.), Synthesis of Formaldehyde, 141
Chapman (F.), the Older Tertiary Foraminiferal Rocks on the West Coast of Santo, New Hebrides, 552
Chapman (H. G.), the Physiology of the Pancreas, 47
Characters, the Inheritance of Acquired, W. Woods Smyth, 152
Charcot (Dr. J.), Antarctic Expedition, 203
Charpentier (P. G.), *Sterigmatocystis nigra* and Oxalic Acid, 392, 480
Cheese, Ripening is due to Moulds and Bacteria in Camembert Type of Soft, 229
Chelifers and House-flies, Prof. Sydney J. Hickson, F.R.S., 629
Chemistry: Practical Methods of Electrochemistry, F. Mollwo Perkin, 5; the Critical Temperature and Pressure of Living Substances, Dr. F. J. Allen, 7; Determination of Neon and Helium in Atmospheric Air, Sir William Ramsay, K.C.B., F.R.S., 21; Chemical Society, 23, 71, 141, 165, 238; Preparation of Terpenes and Related Substances, W. H. Perkin, jun., and S. S. Pickles and K. Matsubara, 23; Estimation of Potassium Permanganate in Presence of Potassium Persulphate, J. A. N. Friend, 23; a Laboratory Manual of Organic Chemistry for Beginners, Dr. A. F. Holleman, 28; a Text-book of Physiological Chemistry, Charles E. Simon, 29; New Researches on Chemical Combination, M. Berthelot, 47; Preparation of Anhydrous Chlorides of the Metals of the Rare Earths, Camille Matignon, 47; Cæsium Amide, E. Rengade, 47; New Reagent for Potassium, Eugenio Pinerua Alvarez, 47; Calcium Nitrate in Agriculture, E. S. Bellenoux, 47; a Combination of Methæmoglobin containing Fluorine, H. Ville and E. Derrien, 47; Camphoryl-*pseudo*-semicarbazide, M. O. Forster and H. E. Fierz, 71; a Condensation Product of Mandelo-

nitrile, F. R. Japp and J. Knox, 71; Atomic Weight of Nitrogen, R. W. Gray, 71; Philippe A. Guye, 119; the Romance of the Nitrogen Atom, Rev. A. Irving, 151; Dr. E. P. Perman, 176; Action of Fluorine on some Compounds of Nitrogen, MM. Moissan and Lebeau, 206; Reactions between Fluorine and the Compounds of Nitrogen and Oxygen, MM. Moissan and Lebeau, 183; Methylation of Gallotannic Acid, O. Rosenheim, 71; Interaction of Hydrogen Sulphide and Sulphur Dioxide, W. R. Lang and C. Carson, 71; Formula of Cyanomaclurin, A. G. Perkin, 71; Increase of the Rotatory Power of Fatty Molecules in Passing to the State of Cyclic Compounds, A. Haller and M. Desfontaines, 71; New Synthesis of Oxalic Acid, H. Moissan, 71; Action of Potassammonium upon Barium Bromide, A. Joannis, 71; Electrolytic Reduction of the Nitrocinnamic Acids, C. Marie, 71; Action of Carbon Monoxide upon Silver Oxide, Henri Dejust, 71; Decomposition of Silver Oxide at High Temperatures, G. N. Lewis, 350; Strontium Ammonium, M. Rœderer, 71–2; a New Osmium Compound, Piñerúa Alvarez, 72; Acetol a Pseudo-acid, André Kling, 72; Action of Metal Ammoniums on the Halogen Derivatives of Methane, E. Chablay, 72; Action of the Metal Ammoniums on Alcohols, E. Chablay, 96; Action of the Metal Ammoniums on the Polyatomic Alcohols, E. Chablay, 119; Relation of Ammonium to the Alkali Metals, A. E. H. Tutton, 165–6; on the Menthones and Menthols obtained by the Reduction of Pulegone by the Catalytic Action of Reduced Nickel, A. Haller and C. Martine, 95; Potato Starch, L. Maquenne and Eug. Roux, 95; Basic Magnesium Carbonates from the Santorin Eruption of 1866, A. Lacroix, 95; a Reaction of Rhodium, Piñerúa Alvarez, 96; Hydrated Platinum Oxide in Reality a Platinic Acid, Dr. Italo Bellucci, 109; Metallic Stannates and Plumbates derived from Similar Acids, Dr. Italo Bellucci and N. Parravano, 109; Efficiency of Method of Synthesising Nitric Acid from the Gases of the Atmosphere Increased by Working with Air under a very Great Pressure, E. Rossi, 109; New Method of Preparing Mesoxalic Esters, Ch. Schmitt, 119; Researches on Animal Lactase, Ch. Porcher, 119; Basicity of Pyranic Oxygen, R. Fosse and L. Lesage, 119; Determination of Oxygen in Sea-water, Neils Bjerrum, 130; Action of Oxygen upon Cæsium-ammonium, E. Rengade, 168; Desmotropic Form of Substances of the Ethyl Acetoacetate Type, J. W. Brühl and H. Schröder, 141; Chlorination of 2-Methylpyridine, W. J. Sell, 141; Chemical Structure and Physical Properties Associated with the Theory of Colour, W. N. Hartley, 141; Thermal Decomposition of Formaldehyde and Acetaldehyde, W. A. Bone and H. L. Smith, 141; Synthesis of Formaldehyde, D. L. Chapman and A. Holt, jun., 141; Constitution of Nitric Acid and its Hydrates, W. Noel Hartley, 142; Physical Properties of Sodium Vapour, P. V. Bevan, 142; Application to Electrolytes of the Hydrate Theory of Solutions, Dr. T. Martin Lowry, 142; Cyanocamphoacetic, Cyanocampho-α-propionic, Cyanocampho-α-butyric Acids and their Derivatives, A. Haller and A. Couréménos, 143; Methylnatalœmodine and Natalœmodine, E. Léger, 143; Acidity of some Ethyl Alcohols of Commerce, René Duchemin and Jacques Dourlen, 143; Examination of Phosphorus Sulphide for the Presence of Free White Phosphorus, Léo Vignon, 143; Physical Properties of Propane, Paul Lebeau, 143; Methyl-acetyl-carbinol, André Kling, 143; the Development of Spectrochemistry, Prof. J. W. Brühl at the Royal Institution, 158; Atomic Weight of Chlorine, Prof. H. B. Dixon, F.R.S., and E. C. Edgar, 165; Action of Chlorine on Boiling Toluene, J. B. Cohen, H. M. Dawson, and P. F. Crosland, 239; Constituents of the Seeds of *Hydnocarpus Wightiana* and of *Hydnocarpus anthelmintica*, F. B. Power and M. Barrowcliff, 165; Constituents of the Seeds of *Gynocardia odorata*, F. B. Power and M. Barrowcliff, 165; New Diamines, G. T. Morgan and W. O. Wootton, 166; Action of Magnesium Methyl Iodide on Pinenenitrosochloride, W. A. Tilden and J. A. Stokes, 166; Estimation of Hydrogen Peroxide in the Presence of Potassium Persulphate, J. A. N. Friend, 166; Replacement of Hydroxyl by Bromine, W. H. Perkin, jun., and J. L. Simonsen, 166; Influence of Phosphates on the Fermentation of Glucose by Yeast Juice, A. Harden and W. J. Young, 166; Gases Liberated on Pulverising Monazite, R. J. Moss, 167; Expansion and Density of some Gases at High Temperatures, the Application to the Determination of their Molecular Weights, Adrien Jacquerod and F. Louis Perrot, 168; Protagon and the Cerebrines and the Cerebric Acid Preexisting in the Nervous Tissue, N. A. Barbieri, 168; Constituents of Manchester Soot, Prof. E. Knecht, 167; Chloride and Bromide of Thorium, H. Moissan and M. Martinsen, 167; Biochemie der Pflanzen, Prof. Friedrich Czapek, F. Escombe, 169; Chitin in the Carapace of *Pterygotus osiliensis*, Dr. Otto Rosenheim, 189; New Method of Preparing Esters, Dr. W. W. Taylor, 191; Mode of Formation of Acetol by the Direct Oxidation of Acetone, M. Pastureau, 192; Action of Sodium on the Esters of the Fatty Acids, M. Bouveault and R. Locquin, 192; Aromatic Substitution Derivatives of Ethylene Oxide, MM. Fourneau and Tiffeneau, 192; Sparteine and its Reaction with Methyl Iodide, Charles Moureu and Amand Valeur, 192; Sparteine the Stereoisomerism of the Two Iodomethylates, Charles Moureu and Amand Valeur, 216; Action of Ethyl Iodide on Sparteine, Charles Moureu and Amand Valeur, 264; Determination of Sulphuric Acid in Soils, J. Howard Graham, 205; an Intensely Radio-active Substance, Actinium X, T. Godlewski, 206; Isomorphous Mixtures of the Tartrates of Thallium and Potassium, Jean Herbette, 216; Alkyl Thujones and the Combinations of Thujone with Aromatic Aldehydes, A. Haller, 216; Influence of Concentration on the Magnetic Properties of Solutions of Cobalt, P. Vaillant, 216; Chemical Properties of the Anhydrous Chloride of Neodymium, Camille Matignon, 216; Death of Prof. P. T. Cleve, 226; Synthesis by Means of the Silent Electric Discharge, J. N. Collie, 238; Combinations of Aluminium Chloride with Carbonyl Chloride, E. Baud, 239; Condensation of Chloral with Aromatic Hydrocarbons under the Influence of Aluminium Chloride, Adolphe Dinesmann, 312; Different States of Oxidation of Aluminium Powder, M. Kohn-Abrest, 360; the Aluminium Steels, Léon Guillet, 264; Steels containing Tin, Titanium, and Cobalt, Léon Guillet, 239; Reduction of Aldoximes, A. Mailhe, 239; Bromination of Paraldehyde, P. Freundler, 239; a Bivalent Phytosterine Alcohol, T. Klobb, 239; Combustion of Sulphur in the Calorimetric Bomb, H. Giran, 239; Hydrolysis of very Concentrated Solutions of Ferric Sulphate, A. Recoura, 239; Synthesis of Substances Allied to Epinephrine, G. Barger and H. A. D. Jowett, 239; Action of Water on Diazo-salts, J. C. Cain and G. M. Norman, 239; Precise Method of Estimating the Organic Nitrogen in Potable Waters, J. C. Brown, 239; Bromine in Solutions of Potassium Bromide, F. P. Worley, 239; Tetramethylammonium Hydroxide, J. Walker and J. Johnston, 239; Ultra-violet Absorption Spectra, Benzene, Dr. E. C. C. Baly and Prof. J. Norman Collie, F.R.S., 239; Ultra-violet Absorption Spectra, the Phenols, Dr. E. C. C. Baly and E. K. Ewbank, 239; Absorption Spectrum of Benzene in the Ultra-violet Region, Prof. W. N. Hartley, F.R.S., 557; Dr. E. C. C. Baly and Prof. J. Norman Collie, F.R.S., 630; Calcium Oxalate in the Eucalyptus Barks, Henry G. Smith, 240; Camphoacetic and β-Camphopropionic Acids, A. Haller, 263; Existence in the Black Elder of a Compound Furnishing Hydrocyanic Acid, M. Guignard, 263; Hydrocyanic Glucoside in the Leaves of the Elder, Em. Bourquelot and Em. Danjou, 264; Nature of the Hydrocyanic Glucoside of the Black Elder, L. Guignard and J. Houdas, 336; Hydrocyanic Acid obtained from Gooseberry Leaves, L. Guignard, 504; Synthesis of the Three Tertiary Dimethylcyclohexanols and of the Hydrocarbons Connected with them, Paul Sabatier and A. Mailhe, 263; New Method of Synthesis of the Monoatomic and Polyatomic Alcohols, V. Grignard, 264; Combinations of Ferrocyanides and Sulphuric Acid, Paul Chrétien, 264; the Acid γ-Aldehydes, E. E. Blaise and A. Courtot, 264; Densities of Carbonic Anhydride, Ammonia and Nitrous Oxide, Philippe A. Guye and Alexandre Pintza, 264; Part Played by the Copper Salt in Deacon's Process of Preparing Chlorine from Hydrogen Chloride, M. G. Levi and V. Bettoni, 277; Auto-catalytic Decomposition of Silver Oxide under the Influence of Heat, Gilbert N. Lewis, 277; the Society of Chemical Industry, 279;

Hydrogenation of the Ketoximes, a Synthesis of New Amines, A. Mailhe, 288; New Preparation of Rubidium and Cæsium, L. Hackspill, 288; Molecular Transformations of Hydrated Ferric Sulphate, A. Recoura, 288; the Gradual Dissociation of Mellitic Acid, A. Quartaroli, 302; Explosions of Mixtures of Coal-gas and Air in a Closed Vessel, L. Bairstow and A. D. Alexander, 311; Action of Ethylamine and *Iso*butylamine on Cæsium, E. Rengade, 312; der Naturwissenschaftliche Unterricht bei uns und im Auslande, Dr. Karl T. Fischer, 333; Wie sind die physikalischen Schülerübungen praktisch zu gestalten? Oberlehrer Hahn, 333; Influence of Water Vapour on the Reduction of Carbon Dioxide by Carbon, O. Boudouard, 336; Sub-iodide of Phosphorus and its Part in Allotropic Transformation of Phosphorus, R. Boulouch, 336; Action of Sodium Sulphite upon Ethanal, MM. Seyewetz and Bardin, 336; Gentiine, George Tanret, 336; Chemical Equilibrium of the System: Ammonia Gas, Isoamylamine Chlorhydrate, Félix Bidet, 336; Catalytic Decomposition of Monochlor-derivatives of Methane Hydrocarbons in Contact with Anhydrous Metallic Chlorides, Paul Sabatier and A. Mailhe, 336; Duty-free Alcohol, Dr. F. Mollwo Perkin, 344; Connection between Atomic Weight of a Substance and the Amount of Secondary Radiation which it Emits when Subjected to the β and γ Rays of Radium, Prof. A. Righi, 350; Researches on Explosives, Sir Andrew Noble, Bart., K.C.B., F.R.S., 358; a Secondary Reaction of the Halogen Organo-magnesium Compounds, Paul Sabatier and A. Mailhe, 359; Conversations on Chemistry, W. Ostwald, 364; Thermochemistry of the Hydrazones, Ph. Landrieu, 392; *Sterigmatocystis nigra* and Oxalic Acid, P. G. Charpentier, 392, 480; Gases Produced by Actinium, A. Debierne, 424; Production of Heavy Liquids with the Alkaline Iodo-mercurates, M. Duboin, 424; Atlas of Emission Spectra of Most of the Elements, Drs. Hagenback and Konen, 426; Recent Advances in the Chemistry of Albumin, Emil Abderhalden, 437; Sal-ammoniac, a Study in Primitive Chemistry, H. E. Stapleton, 452; Cause of Accumulation of Starch in Bruised Apples, G. Warcollier, 452; die Bedeutung des Experimentes für den Unterricht in der Chemie, Dr. Max Wehner, 455; a New Formation of Diamond, Sir William Crookes, F.R.S., 527; Physical Units of Albuminoid Material and on the Part Played by Lime in its Coagulation, G. Malfitano, 528; the Calcium Carbide Industry in France, 541; Apparatus for Generation and Automatic Compression of Oxygen, Prof. d'Arsonval, 541; van 't Hoff's Hypothesis of Osmotic Pressure of Solutions, Prof. A. Battelli and A. Stefanini, 541; the Isolation of Terbium, G. Urbain, 552; Theoretical Chemistry, Prof. Walther Nernst, 555; a Text-book of Chemical Arithmetic, Horace L. Wells, 556; the Physics and Chemistry of Mining, T. H. Byrom, 557; a Systematic Course of Practical Organic Chemistry, Lionel Guy Radcliffe and Frank Sturdy Sinnatt, 570; Isostrychnine, A. Bacovesco, 600; Index Phytochemicus, Drs. J. C. Ritsema and J. Sack, 603; Derivatives of Cyclohexane, P. Freundler and E. Damond, 624; Sambunigrin, Em. Bourquelot and Em. Danjou, 624; Report of the Principal Chemist upon the Work of the Government Laboratory for the Year Ending March 31, 1903, 634; the Absolute Desiccation of Vegetable Products, L. Maquenne, 648; Halogen Compounds of Dinaphthopyryl with Metals and Metalloids, R. Fosse and L. Lesage, 648; Development of Amylase during the Germination of Seeds, Jean Effront, 648; the Synthetic Dyestuffs and the Intermediate Products from which they are Derived, J. C. Cain and J. F. Thorpe, Walter M. Gardner, Supp. to October 19, vii

Chester (Rear-Admiral), Standard Time in Various Countries, 256

Chick (Dr. Harriette), a Study of the Process of Nitrification with Reference to the Purification of Sewage, 117

Chrétien (Paul), Combinations of Ferrocyanides and Sulphuric Acid, 264

Christophers (Lieut.), Parasites of Indian Field Rat, 515

Chromospheric Spectrum, the Ultra-violet, H. Deslandres, 542

Chronology: Utilisation of the Telephone System for the Exact Transmission of Time, M. Guyou, 134; Introduction of a Standard Time on the Railways of India, 181; New Sundial that Tells Standard Time, Prof. Albert Crehore, Sir W. H. Preece, K.C.B., F.R.S., 200

Chrysler (M. A.), Regeneration in Zamia, 65

Circumzenithal Apparatus, MM. Nušl and Fric, 230

Citizen, the, a Study of the Individual and the Government, Nathaniel Southgate Shaler, 578

Clarke (C. B., F.R.S.), Fictitious Problems in Mathematics, 102

Clarke (H. Herbert), Report on the Sanitation and Antimalarial Measures in Practice in Bathurst, Conakry, and Freetown, 67

Clay (Charles M.), Examples in Algebra, 393

Clays and Clay Industries of Iowa, S. W. Beyer, G. W. Bissell, I. A. Williams, J. B. Weems, and A. Marston, 388

Clays and Clay Industries of New Jersey, H. Ries and H. B. Kümmel, 388

Clayton (John), the Cowthorpe Oak, 43

Cleavage, Experiments on Schistosity and Slaty, George F. Becker, 20; Alfred Harker, 152

Cleavage of Slates, the, Rev. O. Fisher, 55

Cleve (Prof. P. T.), Death of, 226

Cliffs near Cromer, Chalk Masses in the, Prof. T. G. Bonney, F.R.S., 8

Clinical and Pathological Observations on Acute Abdominal Diseases, E. M. Corner, 122

Clock and Chronometer by Thomas Mudge, A. Mallock, F.R.S., 91

Clowes (Dr.), the Immunisation of Mice against Cancer, 86

Coal: Digest of the Evidence given before the Royal Commission on Coal Supplies (1901–1905), 395

Coalfields, the North Staffordshire, Memoirs of the Geological Survey of England and Wales, W. Gibson, G. Barrow, C. B. Wedd, and J. Ward, H. W. Hughes, 612

Coal-tar Colour Industry, Organic Preparations and the, J. C. Cain and J. F. Thorpe, Walter M. Gardner, Supp. to October 19, vii

Cockayne (Dr. L.), Vegetation of Open Bay Islands, New Zealand, 540; Thorns merely Xerophytic Structures, 565

Cockerell (Prof. T. D. A.), the British Slugs, 245; the Spread of Injurious Insects, 307

Cogshall (Prof. W. A.), Double Star Observations, 135

Cohen (J. B.), Action of Chlorine on Boiling Toluene, 230

Colajanni (Prof. N.), Latins et Anglo-Saxons, Races supérieures et Races inférieures, 533

Cole (Prof. Grenville A. J.), Growth of Crystals in the Contact-zone of Granite and Amphibolite, 23; an Introduction to the Geology of Cape Colony, 35; Glacial Studies in Canada, Dr. William H. Sherzer, 316; Explorations in Turkestan, with an Account of the Basin of Eastern Persia and Sistan, Raphael Pumpelly, R. W. Pumpelly, Prof. W. M. Davis, and Ellsworth Huntington, 366

College of Applied Science, the Proposed, 250

Collet (Dr. Leon W.), les Concrétions phosphatées de l'Agulhas Bank (Cape of Good Hope), 286–7

Collie (Prof. J. N., F.R.S.), Synthesis by Means of the Silent Electric Discharge, 238; the Ultra-violet Absorption Spectra of Aromatic Compounds, part i., Benzene and Certain Monosubstituted Derivatives, 239; the Absorption Spectrum of Benzene in the Ultra-violet Region, 630

An Indian Garden, Mrs. Henry Cooper Eggar, Dr. Otto Stapf, 125
Animals I Have Known, A. H. Beavan, 125
Queen-rearing in England, and Notes on a Scent-producing Organ in the Abdomen of the Worker-bee, the Honey-bees of India, and Enemies of the Bee in South Africa, F. W. L. Sladen, 126
Physical Experiments, N. R. Carmichael, 126
An Introduction to Elementary Statics (Treated Graphically), R. Nettell, 126
The Elements of the Differential and Integral Calculus, D. F. Campbell, 126
Völkerpsychologie, Wilhelm Wundt, 126
Extracts from the Narrative Reports of the Survey of India for the Season 1902–3, 129
Report for 1904 on the Lancashire Sea Fisheries Laboratory at the University of Liverpool and the Sea-fish Hatchery at Piel, Frank Balfour Browne, 138
Keltic Researches, E. W. B. Nicholson, 145
The Mythology of the British Islands, Charles Squire, 145
The Literature of the Celts, its History and Romance, Magnus Maclean, 145
Weather Influences, an Empirical Study of the Mental and Physiological Effects of Definite Meteorological Conditions, Dr. E. G. Dexter, 147
Le Leman, Monographie Limnologique, Prof. F. A. Forel, 148
Miscellaneous Essays and Addresses, Henry Sidgwick, 149
The Insulation of Electric Machines, H. W. Turner and H. M. Hobart, Prof. Ernest Wilson, 150
Insect Life, a Short Account of the Classification and Habits of Insects, Fred. V. Theobald, 150
The Radial Area-scale, R. W. K. Edwards, 150
A Preparatory Course in Geometry, W. P. Workman and A. G. Cracknell, 150
The Evolution of the World and of Man, George E. Boxall, 150
Physical Deterioration, being the Report of Papers and Discussions at the Cambridge Meeting of the British Association, 1904, on the Alleged Physical Deterioration of the People and the Utility of an Anthropometric Survey, 152
The Camera in the Fields, F. C. Snell, 153
The Bahama Islands, 154
Biochemie der Pflanzen, Prof. Friedrich Czapek, F. Escombe, 169
Mathematische Einführung in die Elektronentheorie, Dr. A. H. Bucherer, Dr. Harold A. Wilson, 170
Experimentelle Elektrizitätslehre, Dr. H. Starke, Dr. Harold A. Wilson, 170
Leitfaden der Physik für die oberen Klassen der Realanstalten, Dr. F. Bremer, Dr. Harold A. Wilson, 170
Streifzüge an der Riviera, Eduard Strasburger, Prof. G. H. Bryan, F.R.S., 171
Recueil d'Expériences élémentaires de Physique, Henri Abraham, 172
The Effects of Tropical Light on White Men, Major Charles E. Woodruff, 172
Handbuch der Heidekultur, Dr. P. Graebner, 173
I Nuovi Indirizzi e le Promesse della Odierna Antropologia, Fabio Frassetto, 173
Catalogue of the Lepidoptera Phalenæ in the British Museum, Sir George F. Hampson, Bart., 174
The Coral *Siderastraea radians* and its Post-larval Development, Dr. J. E. Duerden, 185
The Face of the Earth (Das Antlitz der Erde), Prof. Eduard Suess, 193
A Collection of Papers Communicated to the Academy of Sciences, with Additional Notes and Instructions for the Construction of Phosphorescent Screens, Prof. R. Blondlot, Prof. John G. McKendrick, F.R.S., 195
School Teaching and School Reform, Sir Oliver Lodge, 195
British Bird Life, W. Percival Westell, 196
Riding and Driving, E. L. Anderson and P. Collier, 197
Der Oeschinensee im Berner Oberland, Max Groll, 197
Manual of the Trees of North America (exclusive of Mexico), C. S. Sargent, 197
Vorträge über Deszendenztheorie gehalten an der Universität zu Freiburg im Breisgau, Prof. August Weismann, 200
Les Sarcodinés des Grands Lacs, Eugène Penard, 218
Steam Turbines, with an Appendix on Gas Turbines, Dr. A. Stodola, 219
Bau der Dampfturbinen, Prof. A. Musil, 219
An Angler's Hours, H. T. Sherringham, 220
Botany of Cook's First Voyage, Illustrations of Australian Plants, Sir Joseph Banks, P.R.S., and Dr. D. Solander, F.R.S., 221
Structural and Field Geology, Dr. Jas. Geikie, 223
The New Knowledge, Robert Kennedy Duncan, 241
Trattato di Geodesia Teoretica, Paolo Pizzetti, Captain W. J. Johnston, 242
The Food Inspector's Handbook, Francis Vacher, 243
Manuale dell'Ingegnere Elettricista, Attilio Marro, 243
Poisonous Plants of all Countries, A. B. Smith, 243

The Isomorphism and Thermal Properties of the Felspars, part i., Thermal Study, Arthur L. Day and E. T. Allen, 258
Decorative Art of the Sioux Indians, Clark Wissler, 260
Decorative Art of the Huichol Indians, Carl Lumholtz, 260
The Norwegian North Polar Expedition, 1893–1896, Scientific Results, 265
The Geese of Europe and Asia, Sergius Alpheraky, 266
Le Four Électrique, son Origine, ses Transformations et ses Applications, Adolphe Minet, R. S. Hutton, 267
Elementary Microscopy, F. Shillington Scales, 268
The Practical Photographer's Annual, 1905, 268
Murray's Handbook of Travel-talk, 269
Geology—Processes and their Results, Thomas C. Chamberlin and Rollin D. Salisbury, 289
The Mechanical Handling of Material, G. F. Zimmer, 290
The Fauna of British India, including Ceylon and Burma, 290
The State and Agriculture in Hungary, Dr. Ignatius Darányi, 291
The Treatment of Diseases of the Eye, Dr. Victor Hanke, 292
Die Stellung Gassendis zu Deskartes, Dr. Hermann Schneider, 292
A Text-book of Physics, Heat, Prof. J. H. Poynting, F.R.S., and Prof. J. J. Thomson, F.R.S., 293
The Oxford Atlas of the British Colonies, 293
High Temperature Measurements, H. Le Chatelier and O. Boudouard, 293
Glacial Studies in the Canadian Rockies and Selkirks, Dr. William H. Sherzer, Prof. Grenville A. J. Cole, 310
La Philosophie naturelle intégrale et les Rudiments des Sciences exactes, Dr. A. Rist, 313
Étude sur le Développement des Méthodes géométriques, Gaston Darboux, 313
Sur le Développement de l'Analyse et ses Rapports avec diverses Sciences, Émile Picard, 313
Introduction à la Géométrie générale, Georges Lechalas, 313
Introduction à la Théorie des Fonctions d'une Variable, Jules Tannery, 313
Correspondance d'Hermite et de Stieltjes, 313
Species and Varieties, their Origin by Mutation, Hugo de Vries, 314
The Modern Asphalt Pavement, Clifford Richardson, 316
Die physikalischen Eigenschaften der Seen, Dr. Otto Freiherr von und zu Aufsess, 316
A Catalogue of North American Diptera or Two-winged Flies, J. M. Aldrich, 317
Elementary Experimental Science, an Introduction to the Study of Scientific Method, W. Mayhowe Heller and Edwin G. Ingold, 317
Astronomischer Jahresbericht, Walter F. Wislicenus, 317
Die Lichtsinnesorgane der Laubblätter, Dr. G. Haberlandt, 323
Concimi, Mangimi, Sementi, &c., Commercio frodi e repressione delle frodi, Specialmente in Italia, Italo Giglioli, 324
Field Operations of the Bureau of Soils, 1903, 325
Science and Practice of Agriculture—Farmer's Handbook, T. Jamieson, 325
Abhandlungen zur Didaktik und Philosophie der Naturwissenschaft, Heft 3, der Naturwissenschaftliche Unterricht bei uns und im Auslande, Dr. Karl T. Fischer, 333
A Modern Utopia, H. G. Wells, 337
Thermodynamik, Dr. W. Voigt, 338
Diagrammes et Surfaces thermodynamiques, J. W. Gibbs, 338
Beiträge zur physiologischen Anatomie der Pilzgallen, Hermann Ritter von Guttenberg, E. R. Burdon, 339
Report on the Injurious Insects and Other Animals observed in the Midland Counties during 1904, Walter E. Collinge, 340
Studies of the Museums and Kindred Institutions of New York City, Albany, Buffalo, and Chicago, with Notes on some European Institutions, A. B. Meyer, 340
Notes on Assaying and Metallurgical Laboratory Experiments, Prof. Richard W. Lodge, 340
The Practical Photographer, 341
The Geology of South Africa, F. H. Hatch and G. S. Corstorphine, 346
Manuel Pratique de Cinematique navale et maritime, Captain Leon Vidal, Sir W. H. White, K.C.B., F.R.S., 361
Œuvres complètes de Christiaan Huygens, 362
Manual of Psychiatry, J. R. de Fursac, 363
Experiments with Plants, Dr. W. J. V. Osterhout, 364
Conversations on Chemistry, W. Ostwald, 364
Mathematical Recreations and Essays, W. W. Rouse Ball, 364
Explorations in Turkestan, with an Account of the Basin of Eastern Persia and Sistan, Raphael Pumpelly, Prof. Grenville A. J. Cole, 366
Bird Life Glimpses, E. Selous, 367
Clays and Clay Industries of Iowa, S. W. Beyer, G. W. Bissell, I. A. Williams, J. B. Weems, and A. Marston, 388
The Clays and Clay Industries of New Jersey, H. Ries and H. B. Kümmel, and G. N. Knapp, 388
Easy Graphs, H. S. Hall, 393
The Rudiments of Practical Mathematics, A. Consterdine and A. Barnes, 393
Elementary Practical Mathematics, H. A. Stern and W. H. Topham, 393
A First Algebra, W. M. Baker and A. A. Bourne, 393
Algebraical Grounding, D. E. Shorto, 393
Examples in Algebra, Charles M. Clay, 393
Geometrical Conics, G. W. Caunt and C. M. Jessop, 393
Problems of the Panama Canal, Brig.-General Henry L. Abbot, 394
The American Thoroughbred, C. E. Trevathan, 395
The Story of Reptile Life, W. P. Pycraft, 395
Digest of the Evidence given before the Royal Commission on Coal Supplies (1901–1905), 395
Wasps, Social and Solitary, George W. Peckham and Elizabeth G. Peckham, 395
X-Rays, their Employment in Cancer and Other Diseases, Richard J. Cowen, 395
Neue Abhandlungen über den menschlichen Verstand, G. W. v. Leibniz, 396
Immanuel Kant's Logik, G. B. Jäsche, 396
Lazarus der Begründer der Völkerpsychologie, Dr. Alfred Leicht, 396
Forty Years' Researches in British and Saxon Burial Mounds of East Yorkshire, J. R. Mortimer, 398
The British Moss-flora, R. Braithwaite, 425
Einleitung in der experimentelle Morphologie der Tiere, Dr. Hans Przibram, 426
Atlas of Emission Spectra of Most of the Elements, Drs. Hagenback and Konen, 426
Précis d'Hydraulique—La Houille Blanche, Raymond Busquet, 427
Catalogus Mammalium, tam viventium quam fossilium, E. L. Trouessart, 427
How to Know Wild Fruits, a Guide to Plants when not in Flower by Means of Fruit and Leaf, Maude Gridley Peterson, 428
Marine Engines and Boilers, their Design and Construction, Dr. G. Bauer, 453
Beitrag zur Kenntnis der Vogelwelt Islands, B. Hantzsch, 454
Neue Fische und Reptilien aus der böhmischen Kreideformation, Prof. Dr. Anton Fritsch and Dr. Fr. Bayer, 454
Die Bedeutung des Experimentes für den Unterricht in der Chemie, Dr. Max Wehner, 455
Monographie des Cynipides d'Europe et d'Algérie, l'Abbé J. J. Kieffer, 455
The Gum-bichromate Process, J. Cruwys Richards, 455
Handbuch der geographischen Ortbestimmung für Geographen und Forschungsreisende, Dr. Adolf Marcuse, 481
La Sociologie génétique, François Cosentini, 482
Trees, H. Marshall Ward, 482
A Laboratory Guide in Elementary Bacteriology, Dr. William Dodge Frost, Prof. R. T. Hewlett, 483
Nature-study Lessons for Primary Grades, L. B. McMurry, 483
Einführung in die Vektoranalysis mit Anwendungen auf die mathematische Physik, Dr. Richard Gans, 483

L'Évolution de la Matière, Dr. Gustave Le Bon, 505
The Færöes and Iceland, Studies in Island Life, N. Annandale, 506
Le Système des Poids, Mesures et Monnaies des Israélites d'après la Bible, B. P. Moors, 506
A Primer on Explosives, Major A. Cooper-Key, 507
A Note-book of Experimental Mathematics, C. Godfrey and G. M. Bell, 507
Science Teaching in Elementary Schools, 512
A Treatise on Plague, Dr. W. J. Simpson, Dr. E. Klein, F.R.S., 529
Our Stellar Universe, a Road-book to the Stars, Thomas Edward Heath, 531
Our Stellar Universe (Six Stereograms of Sun and Stars), Thomas Edward Heath, 531
The Crystallisation of Iron and Steel, an Introduction to the Study of Metallography, Dr. J. W. Mellor, A. McWilliam, 532
Latins et Anglo-Saxons, Races supérieures et Races inférieures, Prof. N. Colajanni, 533
Machine Construction and Drawing, Frank Castle, 533
Graphs for Beginners, W. Jamieson, 533
The Topography and Geology of the Fayum Province of Egypt, H. J. L. Beadnell, 535
Ice or Water, another Appeal to Induction from the Scholastic Methods of Modern Geology, Sir Henry H. Howorth, F.R.S., 553
Theoretical Chemistry, Prof. Walther Nernst, 555
Mathematical and Physical Papers by the late Sir George Gabriel Stokes, Bart., 555
Notes on the Drawings for Sowerby's "English Botany," F. N. A. Garry, 556
A Text-book of Chemical Arithmetic, Horace L. Wells, 556
The Physics and Chemistry of Mining, T. H. Byrom, 557
The Annual of the British School at Athens, H. R. Hall, 558
Two Reports on the French Glacier Commission, 561
Setting Type by Telegraph, Donald Murray, 568
On Two Orders of Arachnida, Opiliones, especially the Suborder Cyphophthalmi, and Ricinulei, namely, the Family Cryptostemmatoidæ, Dr. H. J. Hansen and Dr. W. Sörensen, R. I. Pocock, 577
Palaeozoische Arachniden, Prof. Dr. Anton Fritsch, R. I. Pocock, 577
The Citizen, a Study of the Individual and the Government, Nathaniel Southgate Shaler, 578
A Systematic Course of Practical Organic Chemistry, Lionel Guy Radcliffe, 579
Die Entwickelung der electrischen Messungen, Dr. O. Frölich, 579
Zoologischer Jahresbericht für 1904, 579
Examples in Arithmetic, C. O. Tuckey, 580
The Primary Arithmetic, 580
Mechanics, a School Course, W. D. Eggar, 601
Elements of Mechanics, Prof. Mansfield Merriman, 601
An Intermediate Course of Mechanics, A. W. Porter, 601
Field Book of Wild Birds and their Music, F. Schuyler Mathews, 602
Studien über Hautelektricität und Hautmagnetismus des Menschen, Dr. Erik Harnack, Dr. Geo. J. Burch, F.R.S., 602
An Introduction to the Study of Colour Phenomena, Joseph W. Lovibond, 603
Index Phytochemicus, Drs. J. C. Ritsema and J. Sack, 603
Yearbook and Calendar for 1905–6, Essex Field Club, 606
The Coming of Age of the Essex Field Club, 606
Memorias do Museu Goeldi (Museu Paraense) de Historia Natural e Ethnographia, iv., Os Mosquitos no Pará, Prof. Dr. Emilio Augusto Goeldi, 607
A Guide to the Study of Fishes, David Starr Jordan, 625
The Far East, Archibald Little, 626
Handbuch der Spectroscopie, Prof. H. Kayser, 627
Identificación por las Impresiones digito-palmares (La Dactiloscopia), Dr. Alberto Yvert, 628
Science in South Africa, a Handbook and Review, 628
Stone Gardens, Rose Haig Thomas, 629
Oblique and Isometric Projection, John Watson, 629
Influence de l'Alimentation et de l'Humidité sur la Variation des Papillons, Arnold Pictet, 632
Report of the Principal Chemist upon the Work of the Government Laboratory for the Year ending March 31, 1905, 634

LITERARY SUPPLEMENT.

A Tibetan-English Dictionary with Sanskrit Synonyms, Sarat Chandra Das, Lieut.-Colonel L. A. Waddell, Supp. to October 19, iii
Guide to Finger-print Identification, Henry Faulds, Supp. to October 19, iv
Mécanisme et Éducation des Mouvements, Prof. Georges Demeny, Supp. to October 19, v
On the Traversing of Geometrical Figures, J. Cook Wilson, Supp. to October 19, vi
The Synthetic Dyestuffs and the Intermediate Products from which they are derived, J. C. Cain and J. F. Thorpe, Walter M. Gardner, Supp. to October 19, vii
Prinzipienfragen in der Naturwissenschaft, Max Verworn, Supp. to October 19, viii
Das Pflanzenreich, Supp. to October 19, ix
Physiologie des Menschen, Dr. Luigi Luciani, Dr. J. A. Milroy, Supp. to October 19, x

Solander (Dr. D.), Botany of Cook's First Voyage, Illustrations of Australian Plants, 221
Solar Activity, the, 279
Solar Activity, the, January–June, Prof. Mascari, 518
Solar Changes and Weather, Dr. William J. S. Lockyer, 129, 175; A. B. M., 175
Solar Eclipse: Proposed Observation of Mercury during the Solar Eclipse, Dr. G. Johnstone Stoney, F.R.S., 244; Proposed Magnetic and Allied Observations during the Total Solar Eclipse on August 30, Dr. L. A. Bauer, 342; the Forthcoming Total Solar Eclipse, Dr. William J. S. Lockyer, 309, 457; Observations of, in Tripoli, Barbary, Prof. David Todd, 484; French Observations of the Total Solar Eclipse, Prof. Janssen, 518; M. Bigourdan, 518; M. Stephan and M. Trépied, 518; M. Bourget, 518; M. Nordmann, 518; M. Salet, 518; M. Moye, 518; Geodetic Measurements from Solar Eclipses, C. E. Stromeyer, 230; *see also* Astronomy
Solar Origin, Cosmic Dust of, Prof. Schaeberle, 424
Solar Outburst? a, Arthur Mee, 320
Solar Parallax, a Spectrographic Determination of the, F. Küstner, 611
Solar Physics Observatory Eclipse Expedition, the, Dr. William J. S. Lockyer, 508
Solar Radiation, a Proposed New Method for Determining the, Prof. Ceraski, 437
Solar Research, International Union for Cooperation in, 490, 563
Solar Spectrum, Observations of "D_3" in the, Dr. H. Kreusler, 66
Solar Spectrum, Visibility of D_3 as a Dark Line in the, Prof. A. Fowler, 184; A. Buss, 184
Solar and Terrestrial Changes, 249, 332
Solomon (Maurice), Maxwell's Theory and Wireless Telegraphy, H. Poincaré and F. K. Vreeland, 99: Alternating Currents, A. Russell, 99; What Do We Know Concerning Electricity? Antonia Zimmern, 99: Modern Electricity, J. Henry and K. J. Hora, 99; Modern Electric Practice, 99; Electricity Control, a Treatise on Electric Switchgear Systems of Electric Transmission, Leonard Andrews, 99; Setting Type by Telegraph, Donald Murray, 568
Sörensen (Dr. W.), on Two Orders of Arachnida, Opiliones, especially the Suborder Cyphophthalmi, and Ricinulei, namely, the Family Cryptostemmatoidæ, 577
Sowerby's "English Botany," Notes on the Drawings for, F. N. A. Garry, 556
Spanton (W. D.), Physical Deterioration, 332
Species and Varieties, their Origin by Mutation, Hugo de Vries, 314
Spectrochemistry, the Development of, Prof. J. W. Brühl at the Royal Institution, 158
Spectroheliograph Pictures, Interpretation of, M. N. Donitch, 495; Prof. Hale and Mr. Ellerman, 495
Spectroheliograph Results, Recent, Dr. William J. S. Lockyer, 9; Phillip Fox, 183
Spectrum Analysis: Anomalous Dispersion and "Flocculi," Prof. Julius, 19; Observations of "D_3" in the Solar Spectrum, Dr. H. Kreusler, 66; Visibility of D_3 as a Dark Line in the Solar Spectrum, Prof. A. Fowler, 184; A. Buss, 184; New Spectrum Observed in Gadolinium, G. Urbain, 71; Investigation of the Arc Spectrum of Tungsten, Dr. Hasselberg, 134; Dr. H. M. Reese's Observations of "Enhanced" Lines in the Fe, Ti, and Ni Spectra, F. E. Baxandall, 134; Stars with Spectra of the Orion Type, Prof. Pickering, 135; Photographs in Colour of the Spectrum Negative by Transmission, G. Lippmann, 167; Stars with Peculiar Spectra, Mrs. Fleming, 183; Prof. Pickering, 183; the Ultra-violet Absorption Spectra of Aromatic Compounds, part i., Benzene and Certain Monosubstituted Derivatives, E. C. C. Baly and J. N. Collie, 239; part ii., the Phenols, E. C. C. Baly and E. K. Ewbank, 239; the Ultra-violet Chromospheric Spectrum, H. Deslandres, 542; on the Absorption Spectrum of Benzene in the Ultra-violet Region, Prof. W. N. Hartley, F.R.S., 557; a Focusing Screen for Use in Photographing Ultra-violet Spectra, Prof. W. N. Hartley, F.R.S., 581; the Absorption Spectrum of Benzene in the Ultra-violet Region, Dr. E. C. C. Baly and Prof. J. Norman Collie, F.R.S., 630; the Fluorescence of Sodium Vapour, Prof. R. W. Wood, 286; Sun-spot Spectra, W. M. Mitchell, 330; General Principles of Absorption Spectrophotometry and a New Instrument, James R. Milne, 391; Absorption Spectrum of Manganous Salts, P. Lambert, 392; Atlas of Emission Spectra of Most of the Elements, Drs. Hagenback and Konen, 426; Absorption Spectrum and Fluorescence of Mercury Vapour, W. N. Hartley, F.R.S., 504; the Isolation of Terbium, G. Urbain, 552; Influence of Collisions and of the Motion of Molecules in the Line of Sight upon the Constitution of a Spectrum Line, Lord Rayleigh, O.M., F.R.S., 575; Study of the Spectra of Alloys of Different Metals, P. G. Nutting, 591; a Spectrographic Determination of the Solar Parallax, F. Küstner, 611; Handbuch der Spectroscopie, Prof. H. Kayser, 627
Spinthariscope and Retinal Excitability, the, Prof. Francis Gotch, F.R.S., 174
Spirit-level as a Seismoscope, the, G. T. Bennett, 80
Spring and Summer, a Relation between, Alex. B. MacDowall, 56
Spring (Prof. W.), the Limit of Visibility of Fluorescence, 350
Squire (Charles), the Mythology of the British Islands, 145
Staffordshire Coalfields, the North, Memoirs of the Geological Survey of England and Wales, W. Gibson, G. Barrow, C. B. Wedd, and J. Ward, H. W. Hughes, 612

SCIENTIFIC WORTHIES.

XXXV.—EDUARD SUESS.

AMONG the living leaders of geology none is more widely known and more highly honoured than Eduard Suess. The amount and value of his original contributions to science, the broad, philosophic grasp he has displayed of every department of research on which he has entered, the vivid, imaginative insight which has enabled him to marshal a multiplicity of scattered facts into connected order and sequence, the unwearied industry with which he has made himself acquainted with the geological literature of almost every country on the face of the globe, and the noble march of the literary style in which he has clothed not a little of his reasoning and speculation, have combined to give him a place apart, like that of one of the great masters in the heroic age of geology. Full of years and honours, and president of the Academy of Sciences, he still moves as the centre of the scientific life of Vienna, still enriches the world with his impressive pictures of the structure and history of the earth, and still manifests an ardent interest and enthusiasm in all that concerns the advancement of natural knowledge.

But for a wave of change in the world of commerce we might have claimed Suess as an Englishman, and his achievements might have added their lustre to the scientific fame of this country instead of Austria, for he was born in London and spent here the earliest years of his childhood. His father, who was a native of Saxony, had settled here as a German merchant, importing wool from Bohemia, and it was during the residence of the family in London that the eldest son and future geologist was born on August 20, 1831. When wool began to arrive in abundance from the vast sheep-runs of the Australian colonies, the trade in the Bohemian product declined so much that at last, in November, 1834, the Suess family left England for Prague. The father in 1845 became a partner in a great industrial establishment in Vienna, and that city was thenceforth the family home. It had been at first intended that the son should enter the same business, and accordingly at the end of the usual school training he was placed in the polytechnic school. But it soon became apparent that his natural bent did not lie in the commercial direction, but wholly towards natural history studies. As early as the year 1850, when he was only nineteen years of age, he ventured upon his first publication—a short sketch of the geology of Carlsbad and its mineral waters, specially prepared for the use of foreigners. So completely had his tastes now decided his future life that in the following year he was appointed an assistant in the Imperial Museum of Vienna, and thus made his formal entry into the official ranks of science. From that day until now the long intervening half-century, though uneventful in personal experiences, has been with him a time of ceaseless industry and fruitful research. A few more specially notable epochs in his career may here be noticed.

In the vast palæontological collections of the Vienna Museum Suess found a wide domain for the exercise of his powers of observation and comparison. He at first specially devoted himself to the study of the brachiopods of the Palæozoic and Mesozoic formations, and for some ten years continued to publish the results of his researches among these interesting and important fossils, but with incursions into other departments of the animal kingdom, which displayed a general enthusiasm for biological inquiry from the geological point of view. His zeal and ability were soon recognised by his being appointed in 1857, at the age of twenty-six, professor in the university. In 1862 he relinquished his post in the museum and devoted himself thenceforth to the duties of his chair. It was in this early part of his life that he entered upon those studies in palæogeography on which his scientific renown

now largely rests. As far back as 1863 he published a brief statement of the results to which his inquiries had led him as to the former connection of northern Africa with southern Europe. In 1855 he married the daughter of Dr. Strauss, a distinguished physician in Prague, and then entered on a life of great domestic happiness, which largely contributed to the success of a strenuous career wherein science and politics came to be strangely blended.

From his youthful days, when he described the Carlsbad springs, he had been interested in underground waters, and among the inquiries which he pursued while attached to the museum was one that embraced the relations of the soil and water supply of Vienna to the life of its inhabitants. In 1862 he published a small volume on this subject,[1] in which he gave a comprehensive account of the economic geology of the district. At that time the city was suffering from an impure water supply and consequent typhoid fever. The luminous essay of the young professor at once attracted attention. He was the same year elected into the town council, that he might give the benefit of his advice in the steps to be taken towards the attainment of better sanitary arrangements. He boldly advocated a scheme for bringing the abundant pure water of the Alps into Vienna by means of an aqueduct 110 kilometres in length. This project, eventually adopted, was brought to a successful termination in 1873. So grateful were his fellow-citizens for the signal service thus conferred on them that they bestowed on him their highest civic distinction by electing him an honorary burgess. By this time he had made his mark in the town council as one of its most useful and able members, so that it was not surprising that he should have been chosen as one of the parliamentary representatives. For more than thirty years he sat in the Austrian Parliament as a powerful leader of the Liberal party, only retiring in 1896, when advancing age made the strain of the two-fold life as a politician and man of science too great to be longer borne. When the political history of the country during the last half of the nineteenth century comes to be written, a prominent place in it will be given to Eduard Suess.

But it is his scientific work that has to be chiefly dwelt upon here. As an enthusiastic and able teacher he has exerted a notable influence on the successive generations of students at the university, until after forty-four years he resigned his professorship in the summer of 1901. Throughout his career he has shown a keen interest in those branches of geology which more especially deal with the evolution of the earth's surface features. The problems of mountain-building were suggested to him by his excursions among the eastern Alps, and in 1875 his views were so far matured that he published a little volume entitled "Die Entstehung der Alpen." This work contains the germ of those later contributions to science which have placed him on so conspicuous an eminence among the geologists of the day. It sketches the general principles of mountain-architecture, especially revealed by a study of the Alpine chain. But he did not confine his view to the particular area with which he was himself personally familiar. Already his eye looked out on the wider effects of the unequal contraction of the terrestrial crust, and swept across the European continent eastwards into Asia, and westwards across the Atlantic into America. He still held the general belief in the upheaval and depression of continental areas, and dwelt on the evidence of these movements in Scandinavia, which he has since rejected with much elaboration of argument. To thoughtful students of the science this treatise, in its firm hold of detail combined with singularly vivid powers of generalisation, was full of suggestiveness. But the interest and importance of its subject did not obtain general recognition until it was followed ten years afterwards (1885) by the first volume of the great "Antlitz der Erde"—the work which has chiefly given Suess his place among his contemporaries, and by which his name will be handed down to future time.

In its striking arrangement of subjects, in its masterly grouping of details which, notwithstanding their almost bewildering multiplicity, are all linked with each other in leading to broad and impressive conclusions, and in the measured cadence of its finer passages, the "Antlitz" may be regarded as a noble philosophical poem in which the story of the continents and the oceans is told by a seer gifted with rare powers of insight into the past. The order of treatment is not that of a systematic text-book. On the contrary, the casual reader who looks over the contents of the chapters might suppose them to consist of a series of desultory essays with no very clear sequence of thought. Yet a more leisurely study soon shows him how closely interwoven is the texture of the whole composition. He is astonished at the almost incredible range of literature which the author must have consulted, and he finds himself borne onward page after page by the luminous array of facts and the brilliant conclusions drawn from them. From the ancient traditions of the Deluge he is led through other human records, and made to see by what combination of physical conditions changes are worked on the surface of the earth. Upheaval and subsidence, volcanic eruptions, the elevation of mountain-chains, the depression of sea-basins, the structure and disposition of continents, the formation and boundaries of the different oceans in the past as well as at the present day, the successive plications that in the course of geological time have produced the land areas and mountain-ranges of the globe—in short, the gradual evolution of the existing topography of the surface of the globe—this vast theme is here treated with a fulness of knowledge and a breadth of view which are to be found in no other author.

The work at once commanded attention among the geologists of every country, and the influence of its

[1] "Der Boden der Stadt Wien nach seiner Bildungsweise, Beschaffenheit, und seinen Beziehungen zum Bürgerlichen Leben." (Vienna, 1862.)

teaching before long became apparent in geological literature. It was first translated into French in an edition which, thanks to the singular erudition of its editor, M. E. de Margerie, has been so enriched with footnotes as to become an invaluable work of reference for published papers in every department of the wide range of subjects whereof it treats. Within the last few months the first volume of an English translation by Miss Hertha Sollas, under the direction of her father, Prof. Sollas, of Oxford, has been issued by the Clarendon Press. The labours of Prof. Suess are thus placed within the reach of all English-speaking geologists in a version which reads more like an original treatise in our language than as the translation of a German work.

That in covering so wide a field as that of the "Antlitz" the author has necessarily had to rely on recorded observations of unequal value, and that consequently the deductions he has drawn may need to be corrected from subsequently obtained fuller and more accurate data, will doubtless be admitted by no one more frankly than by himself. But even in regard to questions which have long been discussed, and regarding which abundant facts have long been known, there is room for different interpretations from those which the professor has adopted. Thus the phenomena of submergence and emergence of land in Sweden and the basin of the Baltic are treated by him in great fulness and with much ingenuity, but he arrives at conclusions strongly opposed to those to which prolonged study has led the northern geologists. This problem is one of fundamental importance in regard to our conceptions of the nature of the movements to which the surface of the globe is subject, and it is much to be desired that some general agreement in regard to it should be attained.

Nevertheless, apart from differences of opinion, which are inseparable from the growth of such a science as geology, and even where one may be most disposed to dissent from the views of Prof. Suess, the transcendent value of his life-long labours is none the less vividly realised now by all who have studied his writings. Their importance in the history of science will assuredly be no less fully acknowledged by the future generations who will gain from them inspiration and enlightenment. Meanwhile, he has the satisfaction of abundant recognition from all civilised countries. The learned societies of Europe have vied with each other in doing him honour, and not the least prominent among them has been our own Royal Society, which ten years ago elected him as one of its foreign members, and in the year 1903 awarded him the Copley medal—the highest distinction which it has to bestow. The "Antlitz" is not yet completed, but the second part of the third volume is far advanced. Let us trust that years of rest and quiet work are in store for the illustrious geologist, and that he may live to finish his work amidst the hearty congratulations of the many fellow-workers who look up to him as their master.

ARCH. GEIKIE.

THE RUDIMENTS OF BEHAVIOUR.

Contributions to the Study of the Behaviour of Lower Organisms. By Prof. Herbert S. Jennings. Pp. 256. (Washington: Carnegie Institution, 1904.)

THE author has been for about ten years a careful observer of the rudiments of behaviour which are exhibited by unicellular and other relatively simple animals, and we have read with interest several of his previous studies on the reactions of infusorians and the like to various sets of stimuli. The general impression conveyed was that infusorians and the like gave evidence of an exceedingly simple and stereotyped mode of behaviour—a mere reaction method. When effectively stimulated by agents of almost any kind, the animalcule moves backwards and turns to a structurally defined side of its minute body, while at the same time it may continue to revolve on its long axis. In relation to all sorts of stimuli, the behaviour seemed exceedingly simple and machine-like. But Prof. Jennings has been gradually discovering that the simple reaction-formula does not cover all the facts, and he now gives us news which seems almost too good to be true.

He finds that even among unicellulars "the behaviour is not as a rule on the tropism plan—a set, forced method of reacting to each particular agent—but takes place in a much more flexible, less directly machine-like way, by the method of trial and error." This is a momentous conclusion, notably in relation to comparative psychology. The data are foundation-stones for the science of animal behaviour, and the author is to be congratulated on his demonstration that the ways of even very simple creatures are more than series of "tropisms."

In his "Introduction to Comparative Psychology" (1894), Dr. Lloyd Morgan told the story of his dog's attempts to bring a hooked walking stick through a narrow gap in a fence. The dog "tried" all possible methods of pulling the stick through the fence. Most of the attempts showed themselves to be "error." But the dog tried again and again, until he finally succeeded. He worked by the method of trial and error; and so, Prof. Jennings now assures us, do the infusorians.

"This method of trial and error involves many of the fundamental qualities which we find in the behaviour of higher animals, yet with the simplest possible basis in ways of action; a great portion of the behaviour consisting often of but one or two definite movements, movements that are stereotyped when considered by themselves, but not stereotyped in their relation to the environment. This method leads upward, offering at every point opportunity for development, and showing even in the unicellular organisms what must be considered the beginnings of intelligence and of many other qualities found in higher animals. Tropic action doubtless occurs, but the main basis of behaviour is in these organisms the method of trial and error."

This is not the first time that the dawning of intelligence has been discovered in the Protozoa, but on previous occasions the discovery has been reported by casual observers or by investigators unacquainted with the tropisms. Prof. Jennings has made a special

study of the tropisms, and we find him declaring that it is almost impossible to describe the behaviour of the unicellulars intelligibly without using terms like "perception," "discrimination," and "intelligence." Of course these are used in an "objective sense," and "when their objective significance is kept in mind there is no theoretical objection to them, and they have the advantage that they bring out the identity of the objective factors in the behaviour of animals with the objective factors in the behaviour of man."

From our point of view, Prof. Jennings does not strengthen his position by using these pre-occupied psychological terms; "'perception' of a stimulus," he says, "means merely that the organism reacts to it in some way; 'discrimination' of two stimuli means that the organism reacts differently to them; 'intelligence' is defined by the objective manifestations mentioned in the text." But this does not seem to us the sound line of progress; it leads back to saying that the lucifer match perceives the sandpaper on the box. It seems safer, in the meantime, to say that infusorians alter their behaviour, and alter it effectively, in respect to their experience.

"Stentor does not continue reacting strongly to a stimulus that is not injurious, but after a time, when such stimulus is repeated, it ceases to react, or reacts in some less pronounced way than at first. To an injurious stimulus, on the other hand, it does continue to react, but not throughout in the same manner. When such stimulus is repeated, Stentor tries various different ways of reacting to it. If the result of reacting by bending to one side is not success, it tries reversing the ciliary current, then contracting into its tube, then leaving its tube, &c. This is clearly the method of trial and error passing into the method of intelligence, but the intelligence lasts only very short periods."

With such difficult subjects any evidence of the registration of experience was not to be expected, and the author is to be congratulated on having discovered considerable evidence in support of the thesis that the behaviour of unicellulars is largely a method of trial and error, one reaction by trial and error becoming the basis for a succeeding reaction. This is surely a pathway leading to the high-road of intelligence.

It is easy to make an inanimate system—a little potassium pill on a basin of water, or a tiny wound-up engine on a smooth table—which, once set a-going, will charge against an obstacle, will fail to overcome this, will recoil passively and charge again, and some observers have thought that, *mutatis mutandis,* the animalcule did little more. But Prof. Jennings has shown that the infusorian, in relation to its experience of "error," changes its little tactics, and changes them again, until it succeeds. In a word, it profits by experience. The very essence of vitality, as Spencer pointed out, is in effective response to environment; but when we find an infusorian "trying" one response after another, abandoning those that spell "error," we cannot but feel that vitality has been raised to a second power; it is just beginning to be intelligent. The infusorian is more than a tropic automaton, it is playing a little game of tactics; perhaps if we could educate one it would develop the rudiments of strategy. It is, of course, extremely difficult to keep to a scrupulous objective record of what occurs, but we incline to think that Prof. Jennings has supplied what comparative psychologists have been waiting for, namely, quite trustworthy accounts of the beginnings of selective or controlled behaviour.

"The method of trial and error involves some way of distinguishing error, and also, in some cases at least, some method of distinguishing success. The problem as to how this is done is the same for man and for the infusorian. We are compelled to postulate throughout the series certain physiological states to account for the negative reactions under error, and the positive reactions under success. In man these physiological states are those conditioning pain and pleasure. The 'method of trial and error' is evidently the same as reaction by 'selection of over-produced movements,' which plays so large a part in the theories of Spencer and Bain, and especially in the recent discussions of behaviour by J. Mark Baldwin. The method of trial and error, which forms the most essential feature of the behaviour of these lower organisms, is in complete contrast with the tropism schema, which has long been supposed to express the essential characteristics of their behaviour."

Instead of referring in detail to the author's studies—(1) reactions to heat and cold in the ciliate infusorians; (2) reactions to light in ciliates and flagellates; (3) reactions to stimuli in certain rotifers; (4) the theory of tropisms; (5) physiological states as determining factors in the behaviour of lower organisms; and (6) the movements and reactions of amœbæ—we have sought to explain the chief result of his studies in the infant school of life, and to emphasise its importance in relation to the general theory of animal behaviour. Prof. Jennings has rescued the animalculæ from the bonds of automatism too hurriedly thrust on them, and has afforded a secure basis for the study of the evolution of intelligence.

J. A. T.

MECHANISM.

Mechanism. By Prof. S. Dunkerley. Pp. vi+408. (London: Longmans, Green and Co., 1905.) Price 9s. net.

WRITERS of text-books on mechanism have, of late years, been much influenced by the views of Realeaux on the classification of mechanisms, and the present work shows clearly the impress of these views; but the author has not hesitated to depart from the order in which Realeaux presented his theory of machines in order to suit the needs of beginners, who are apt to find the elaboration of the systematic theory somewhat dry if not accompanied by a wealth of illustration drawn from actual machines, even if these contain elements the properties of which have not been fully explained.

The author, as appears from his preface, is fully alive to the difficulties which the logical treatment of the subject presents, and he expressly states that his work is not intended to be a philosophical treatise on the subject.

From this standpoint the arrangement of the sub-

ject-matter appears to be quite a proper one, for at the present time almost everyone is familiar with the elementary properties of gear-wheels, clutches, the mechanism of steam engines and the like, because of their increasing use in everyday life, and more especially of late, owing to their applications to self-propelled vehicles. On the other hand their less obvious, although not less important, properties are possibly not so well understood; thus, to take a single instance, the conditions to be satisfied in order to produce true rolling motion by gear wheels require a knowledge of the properties of various curves, and this latter subject may well be left to a later stage, as is done in the present work, although it need not prevent a study of machines containing gear wheels when this knowledge is not absolutely necessary for the purpose. The author has therefore described many machines using higher pairing quite early in the book, and has left the more detailed examination of some of the elements for later chapters; this adds very much to the general interest of the reader, while its drawbacks are small. The work opens with an introductory chapter in which the usual definitions occur relating to machines, kinematic chains, lower and higher pairs, and the like, and this is followed by a chapter which is exceedingly interesting on simple machines and machine tools.

Chapters iii. and iv. deal chiefly with mechanisms of the quadric crank and double slider crank chain forms, all those possessing important geometrical properties being grouped together. Naturally the pantograph finds an important place here, and to amplify this section there are descriptions of the copying lathe and also a machine on the same principle for drilling square and hexagon holes. In a future edition it might be worth while to insert, in a suitable place, an account of the epicyclic trains which form an essential part of some machines for turning nuts and bolts to a practically perfect square or hexagon section.

The next two chapters deal with velocity and acceleration diagrams, and we are sure that all students of mechanism will feel greatly indebted to the author for the clear manner in which he has presented this part of the subject. The remainder of the book deals with gear wheels, non-circular wheels and cams, and these are discussed on the usual lines. There is also a section devoted to gear-cutting machinery, which gives an interesting account of this special branch of machine tool work.

It is somewhat remarkable that no place is found in the book for the consideration of so fundamental a subject as the degrees of freedom possessed by a body and the applications which follow from a recognition of these principles in geometrical slides and clamps, such as are described in Thomson and Tait's "Natural Philosophy." Ignorance of these fundamental principles has been one of the most fruitful causes of bad design in mechanism.

The illustrations are mainly line drawings, exceedingly well adapted for descriptive purposes, and with a few exceptions the photographs of machinery are clear and distinct. A series of numerical examples at the end of the book will be of much value to students.

The author has succeeded in writing a valuable text-book on mechanism which will repay a careful study by engineers and others who wish to obtain a knowledge of something more than the elements of this branch of science.

E. G. C.

PRACTICAL ELECTROCHEMISTRY.

Practical Methods of Electrochemistry. By F. Mollwo Perkin. Pp. x+322. (London: Longmans and Co., 1905.) Price 6s. net.

ELECTROCHEMICAL methods, both of analysis and preparation, have in recent years undergone such rapid development, and have reached such a degree of importance, that systematic instruction in their employment has become an indispensable part of the training of the modern student of chemistry. This book, therefore, forms a welcome addition to the ordinary laboratory manuals.

After a general account of electrical magnitudes and units, measuring instruments, and electrolytic apparatus, the author gives practical instructions for electrochemical analysis. The conditions for the quantitative electrodeposition of the individual metals are first discussed; then follows a section on quantitative oxidation and reduction at the electrodes, and, finally, directions are given for the separation of metals from mixed solutions of their salts. The last and longest section of the book deals with preparative electrochemistry. The primary subdivision of the subject is into the preparation of inorganic and of organic compounds, the latter section being treated in three chapters on organic electrolysis, reduction of organic compounds, and oxidation of organic compounds respectively.

The practical instructions are on the whole adequate and accurate, so that the student could acquire with little assistance a sufficient acquaintance with the working methods of electrochemistry. Whilst the book is satisfactory in this, the most important, feature, it shows in other respects many signs of hasty composition, which greatly detract from its value. For example, there are frequent evidences of haste in the treatment of electrical units. In the table on p. 9 the heading of the last column but one is "electrochemical equivalent per coulomb in mg. per sec."; the words "per sec." are not only superfluous but misleading. On p. 29 we find "1 kilowatt=101.93 kilogrammeters," and "1 horse-power is 75 kilogrammeters," where the words "per second" should have been added in both cases. Nothing is more detrimental to clear thinking on the part of the student than slipshod statements of this kind. Again, in the table of "useful data" on p. 286 we find "1 kilowatt=1000 watt-hours," and "volt × amperes=watts." Such data are the reverse of useful. A curious batch of mistakes is to be found on pp. 231–232. It is stated on p. 231 that the electrolyte for the preparation of diethyl succinate is "*acid* potassium or sodium malonate" instead of "*ethyl* potassium or sodium malonate." On the same page we twice find "*diethyl adipic acid*" instead of *diethyl adipate*, and on the succeeding pages a similar error

is repeated. On pp. 226–227 it is surely wrong to ascribe the formation of the trace of ethylene found during the electrolysis of an acetate to the same cause as that which produces the plentiful yield of ethylene during the electrolysis of a propionate. The fact that equation v. is divisible by 2, and that equation iv. is not so divisible, is almost in itself sufficient evidence that the actions are of essentially different character. It is somewhat surprising to find that the kathodic reduction of nitrites, nitrates, and arsenical compounds finds treatment under the heading "Metals deposited as Oxides at the Anode" (pp. 145–150). These and similar slips are minor blemishes; but it is to be hoped that the author will subject his book to a thorough revision for their removal when a second edition is called for.

The references to original papers are numerous, and a convenient table of five-figure logarithms, with instructions for its use, is contained in an appendix. The value of the table might be still further augmented by the inclusion of instructions for the use of the decadic complements of logarithms, a device of which the chemical student is almost invariably ignorant.

OUR BOOK SHELF.

Das Alter der wirtschaftlichen Kultur der Menschheit, ein Rückblick und ein Ausblick. By Ed. Hahn. Pp. xvi + 256. (Heidelberg: Carl Winter, 1905.) Price 6.40 marks.

In the opinion of Dr. Hahn, well known as the inquirer who revolutionised our ideas on the so-called "three stages"—hunting, pastoral pursuits, agriculture—the mass of the reading public will not change its traditional views on pre-history and primitive culture unless the specialist is prepared to do more for it than issue specialist literature. With the object of making propaganda for his views on the domestication of animals, the forms of cultivation, the transition from hoe-cultivation to plough-cultivation, the invention of the plough, the use of the ox as draught-animal, the share of woman in primitive culture, and especially the development of personal property, Dr. Hahn has written the present work, and his object in so doing is commendable. Even specialist literature, however, is not above all considerations of form and logical sequence of ideas; in an *oeuvre de vulgarisation* it is *à fortiori* necessary that there should be an orderly development of facts and of the conclusions to be drawn from them; and this, unfortunately, Dr. Hahn has not given us. Not only is the book in places indigestibly full of facts the connection of which with the main argument is not always made clear, but too much is attempted; to the list of subjects given above must be added the description of the economic conditions and interrelations of China, Babylonia, India, and Egypt, a discussion of the origin of the wheel and the waggon, much polemical matter, dealing with criticisms which the public has never read, and finally excursuses on the fiscal question, socialism, and other subjects unconnected with his immediate purpose. It would be unfair to deny that the book is interesting and stimulating, but it is rather a *causerie* than an exposition of the author's theories. This is the more unfortunate because his views on the domestication of animals, the forms of cultivation, and the stages of economic evolution are largely accepted. From mere lack of literary skill Dr. Hahn will leave his readers comparatively unmoved. As an example of the deficiencies of the book we may mention that the process of domestication of cattle is dismissed with a mention. Many of the author's theories are improbable; it is unnecessary to suppose that the curved horns imitating the shape of the crescent moon first led to the sacro-sanctity of cattle; there are animal cults everywhere. Personal property, even in vegetable food, was known before domesticated plants; the Australian natives store up *bunya-bunya* nuts. We do not need to look to the apparent motion of the stars for the explanation of the origin of Babylonian god-processions, which are a natural method of disseminating the holy influence. The connection of sexual ideas with agriculture may be secondary; syncretism is disregarded in this and other instances. It may not be out of place to say that a few maps of culture areas would have been very helpful, and not to the general reader only.

N. W. T.

Infantile Mortality and Infants' Milk Depôts. By G. F. McCleary, M.D., D.P.H. Pp. xiv + 135. (London: P. S. King and Son.) Price 6*s.* net.

The publication of the evidence before the Inter-Departmental Committee on Physical Deterioration has directed general attention to such subjects as infant feeding. The decreasing birth rate and the appallingly high death rate among infants are dealt with by the author in the earlier chapters of his book.

An increasing number of mothers are unable to nurse their children, so that some method of artificial feeding has to be adopted. The death rate in 1904 among children under one year was 140 per 1000 births, and even these figures by no means represent the total evil, for many of the survivors must be seriously affected. How can this fearful waste of life be stopped? Dr. McCleary deals with one solution, viz. the establishment of depôts worked by the municipality and partially rate-supported. It is generally agreed that cow's milk is the best substitute for human milk. Various opinions are held as to the degree of modification that may be necessary, but pure cow's milk is the *basis* from which to work.

Even if a pure milk were on the market the poor could not afford to buy it. The question of State assistance arises. Dr. McCleary leaves the moral question as to whether it is for the ultimate good of a people to relieve them of their parental duties. Within the compass of 130 pages he wisely restricts himself to the practical working of the depôts, and as he speaks with knowledge of the Battersea depôt his testimony is of interest. In France the milk depôt system is carried out to a considerable extent, unmodified sterilised milk usually being supplied (Budin's method). In America the tendency is to follow Rotch in giving modified unsterilised milk.

The author repeats the necessary warning that a dirty milk is not made clean by sterilisation, and from this it follows that no depôt is on a satisfactory basis unless it has absolute control of its own milk supply. Dr. McCleary advocates much more stringent supervision of the general milk supply, and the establishment of municipal depôts on the lines of that at Rochester, U.S.A.

The book is well illustrated.

A Critical Revision of the Genus Eucalyptus. By J. H. Maiden. Parts i. to v. Pp. iv + 146. (Sydney: W. A. Gullick, 1903–4.)

The classification of the Australian eucalypts presents similar difficulties to those which confront the botanist who undertakes the arrangement of the Hieracia or Rubi of our native flora, with the additional disadvantages that the eucalypts are trees or shrubs, and their distribution is more extensive. In the cir-

cumstances it is natural that monographers should have expressed diverse opinions as to the limits of the species, and that different characters and parts of the plant should have been taken as a basis for classification. Bentham grouped the species according to the shape and mode of dehiscence of the anthers, and von Mueller followed his lead. Prof. Tate has proposed a system based upon the structure of the fruit, whilst of vegetative characters, the cotyledons, leaf-veins, stomata, gums, and timber have all been tested in the hope of finding satisfactory criteria. Mr. Maiden attaches considerable importance to the bark and timber for the guidance of the forester, but recognises that the anthers and fruit are the best characters for the systematist.

In the present monograph the object of the author has been to include, with a description of the important characters, the substance of all recorded observations and investigations which might assist in determining the position and value of species or varieties. Synonyms are considered in detail, with the original description of each where it has been proposed as a species, and the range of each species is noted; finally, the author's views are crystallised in a discussion of the affinities of allied species. These views are based not only on the examination of specimens from important herbaria, but also upon much careful study of the growing trees in their native localities. Whilst recognising the desire of the author to render the work as comprehensive as possible, it must be said that its practical value would be increased by a considerable reduction in the amount of material, in the size of print and in the spacing. The five parts issued amount to 145 pages, and contain twenty-four plates for eight species, so that the complete work will be bulky and exclusive as to price. It may be suggested that a supplement to this treatise in the shape of a compendium suitable for foresters and students generally would be most useful.

Hymenopteren-Studien. By W. A. Schulz. Pp. 147. (Leipzig: Engelmann; London: Williams and Norgate, 1905.) Price 4s. net.

THE present work consists of three essays, the first relating to African Hymenoptera (chiefly Vespidæ and Fossores), the second describing new genera and species of Trigonalidæ, and the third discussing Vespidæ and Apidæ from the Amazons. The work is chiefly descriptive, and will hardly appeal to any but specialists, who must of course consult it when working at the faunas and groups which are discussed in it.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The High-frequency Electrical Treatment.

THE inquest on a lady who died in the Charing Cross Hospital on April 11 must be of interest to those who employ the high-frequency electrical treatment. The report of the case in the *Standard* of April 17 is as follows:—"On April 11 she (the deceased) was under treatment, lying on the electrical couch. Suddenly witness observed the perspiration break out on her face, and immediately stopped the current. He watched her for a while, and as she seemed to be in a collapsed state he administered a spoonful of sal volatile. Then he recognised symptoms which pointed to 'a serious state of affairs,' and sent for Dr. Bailey. The lady was removed to another ward and died in the evening. Death was caused by hemorrhage of the brain, following a rupture of an artery. This was not a consequence of the electrical treatment; she would probably have died just the same if she had been sitting in the waiting-room, instead of on the electrical couch. It was a mere coincidence. Dr. Bailey and Dr. Freyberger gave evidence supporting this view of the case." The treatment was that of the high-frequency electrical current.

Now that high-frequency electrical discharges are much employed in medical work, being the newest and most up-to-date method of treatment for many diseases, it is somewhat important that even "mere coincidences," such as that cited, should not be overlooked or treated lightly; it is only by collecting evidence on such points that any real knowledge respecting the action of the treatment can be obtained. Shortly after the experiments of N. Tesla on electrical discharges, I carried on many experiments on the subject, and from somewhat painful experience I have learned that one source of trouble may be overlooked by many, since it is a secondary action, so that while the utmost attention may be given to the behaviour of the discharge itself, but little may be given to the action of the air which has been subjected to an electrical discharge. The danger of breathing such air was pointed out by me long ago (NATURE, 1896), and by many other workers with electrical discharges since then. Air which had been acted on by the high-frequency discharge, when breathed, caused irritation to the throat and lungs, and a feeling of suffocation, in some cases very severe. This is rather to be expected, since ozone and ozonised air act on blood, albumen, and organic substances readily. Profs. Roscoe and Schorlemmer write thus in their treatise on "Chemistry," p. 243, vol. i. (subject, ozone):—"Whilst blood is completely decolorised, the albumen being entirely, and the other organic matters being nearly all destroyed.")

The trouble mentioned was removed to a considerable extent by inducing a strong draught of warm air across the chamber where the apparatus was used. I feel that I am taking a great liberty in suggesting anything to the high-frequency specialist, who will give me at once the reason why self-induction is expressed as "a length," and why a rapidly varying electromagnetic field causes flashes of light to be seen when the head is placed in such a field. I would suggest that in connection with the method of treatment with the high-frequency discharge, all evidence of new phenomena should be collected and sifted in a scientific spirit, whether it be for or against it.

Operators now take every possible precaution to guard themselves against the evil effects of the X-ray, which at first was treated as quite innocuous. May not the high-frequency discharge in a modified form have a somewhat similar kind of action, and should it not be treated with as much, or at least some, caution?

F. J. JERVIS-SMITH.

The Critical Temperature and Pressure of Living Substances.

IT is well known that living substance is in a labile state, its constructive or destructive metabolism being determined by minute changes, sometimes of temperature or pressure, sometimes of other dynamic conditions. But Mr. Geoffrey Martin's suggestion (NATURE, April 27, p. 609) that the lability is due to the great number of atoms in the molecules of living substance, or to the complex "carbon compounds" present, gives only a partial explanation.

The decomposition of a chemical compound under raised temperature, diminished pressure, &c., depends not only on the size and complexity of the molecules, but also on the tendency of the atoms to re-arrange themselves and form more stable compounds, generally with dissipation of energy. For instance, the paraffins with large molecules are fairly stable, the products of their decomposition being hydrocarbons still. Fatty acids with equally large molecules are less stable, for there is a tendency to split off substances of higher oxidation, leaving a hydrocarbon residue. This tendency increases with the increase of oxygen in compounds, and so the small molecule of glucose is less stable than the large molecule of fatty acid. The presence of nitrogen is often a cause of instability, especially when the nitrogen forms a link between elements (or groups) of opposite polarity; and the instability is most marked when the nitrogen is combined with oxygen on the

one hand, and with carbon and hydrogen on the other, as in the explosives, *e.g.* nitroglycerine.

Living substance has apparently all the above mentioned sources of instability, and perhaps not the least important is that it has for its pivot nitrogen, the element which above all others is remarkable for the lability of its compounds. I have elsewhere[1] indicated the probability that the active molecule of living substance consists of an enormous complex of proteids, carbohydrates, &c., linked together by means of the nitrogen atoms, and that the oxygen store is more or less combined with the nitrogen. At the death of the molecule its constituent groups (proteids, &c.) are released, and the store of oxygen passes from the nitrogen into other and more stable forms of combination.

Chalk Masses in the Cliffs near Cromer.

AT the present time the cliffs near Cromer exhibit some interesting chalk masses in the Glacial drifts. Between East and West Runton Gaps are several of great size and remarkable in position. One, a very long slab-like mass, is bent from being nearly horizontal until it is almost vertical, and thus comes to within a short distance of the top of the cliff. The masses near Trimingham will now repay a close study, for they have changed greatly during the last five years. Both my friend, the Rev. E. Hill, and I have made notes and rough sketches, with the intention of sending to the *Geological Magazine* a short account of what can now be seen; but we earnestly hope that some geologists who are adepts at photography will visit both localities at the earliest possible opportunity, in order to secure a permanent and accurate record of these exceptionally interesting sections.

T. G. BONNEY.

The Rigidity of the Earth's Interior.

THE letter of Dr. T. J. J. See (NATURE, April 13, p. 559) deals with a subject of profound interest to students of the larger problems connected with physical geology. But it appears that, in Dr. See's treatment of the subject, he has overlooked an important point, which I dealt with in a paper read before Section C of the British Association at Birmingham in 1886. Therein I directed attention to the fact that "gravitation" is only a special instance of the law of universal attraction, and as a corollary to this, at any considerable depth within the sphere of the earth, an appreciable factor of what I may call negative gravity must be allowed for, owing to the counter-attraction of the mass of matter situated nearer the surface of the sphere; so that a body placed at the centre of gravity of the earth, whatever its mass or density, would have no weight at all.

I am glad to see that the consideration of "critical temperatures" of *quasi*-solids (the importance of which was emphasised in my little work on metamorphism some fifteen years ago) is receiving serious attention, and I may also point out that the idea of a potentially liquid (or even gaseous) condition of a mass at depths in a practically rigid state is not new; it was treated in a masterly way by Prof. Albert Heim, of Zürich, some twenty years ago, in his magnificent work "Ueber den Mechanismus der Gebirgsbildung." "Ueberlastet" is the word used by Heim to express such conditions, where the pressure is so far "hydrostatic" as to consist of compression acting equally (for the time being) in all directions. Any disturbance in a given portion of the lithosphere of the equilibrium thus existing must result in *shearing movement* if the disturbance be small, and in *flow* in a given direction if the relief in that direction from pressure is great and rapid enough. In the former case we should get "metataxic change," in the latter schistosity; for I still challenge the statement, made recently by a high authority, that "it is only a question of degree between the cleavage of a slate and the foliation of a crystalline schist or gneiss."

Questions relating to tidal action in the rotating lithosphere, and even Lord Kelvin's oft-repeated objection on that ground to the impossibility of any considerable portion of the lithosphere being fluid, because the earth does not undergo the deformation which the physicist would expect owing to the tidal action which should be set up within it, might possibly be seen in a fresh light on taking into account the remarkable facts demonstrated by Prof. John Perry in his lecture on spinning tops, which he gave to an audience of working men on the occasion of the meeting of the British Association at Leeds in 1890. As a "working man" in a real sense of the word, I considered myself privileged to attend that lecture, and was rewarded by finding in my own mind a great difficulty cleared up by Prof. Perry's masterly demonstrations of the practically rigid condition of non-rigid bodies, if only made to rotate with sufficient rapidity, as the equatorial regions of the earth do—something like 1000 miles an hour.

Bishop's Stortford, April 17.

A. IRVING.

Rival Parents.

A CURIOUS example of the rival claims of a pair of thrushes and a pair of blackbirds for the parentage of a young blackbird is being observed in my garden.

A pair of blackbirds built a nest in a small thick laurel, and in another shrub, some 4 feet off, a pair of thrushes also built a nest. The young in both nests were hatched out at the same time, and were successfully reared until they were some eight or nine days old, when a cat attacked the nests (Monday, April 17), killing all the young thrushes and all the blackbirds except one, which was found hidden under the shrubs. It was continually visited after the tragedy by both the old thrushes and old blackbirds, and two or three hours later was removed in some way not observed to a shrubbery twenty or thirty yards away. There for the last five days it has been fed and looked after by both pairs of birds, who mob with exceptional vigour any intruding cat or dog. The young bird seems to have thriven mightily under the attentions of its true and foster parents, who appear in no way to be jealous of one another.

KENNEDY J. P. ORTON.

University College of North Wales, Bangor, April 21.

The Measurement of Mass.

IN the notice of my little book, "Radium Explained," on April 6, twenty-nine lines are devoted to showing that I have reached a wrong conclusion through not knowing that mass is measured by inertia, and I am corrected in these words:—"how is the quantity of matter to be ascertained? The choice practically lies between defining mass by inertia at a given speed or by gravity. . . . As, however, gravity depends on local circumstances, while inertia (at given velocity) does not, the latter property is preferred for the definition of mass, as being more fundamental." So far from rejecting this principle, I state it, in almost the same terms, on p. 84 of my book:—"Mass, or quantity of matter, is usually ascertained by weighing. But weight is merely the force with which the earth attracts, and this varies with our position on its surface. To get an absolute test of mass, which would be independent of position, we may measure the force required to move or stop a body at a certain speed." And nowhere in the book have I supported any argument by the repudiation of the principle here clearly stated. This is a question of fact; the other objection taken is equally ill-founded, but, being on a controversial point, it cannot be dealt with so briefly.

W. HAMPSON.

Properties of Rotating Bodies.

PROF. W. H. PICKERING, in NATURE of April 27 (p. 608), refers to the property which a rotating body possesses of assimilating, in certain circumstances, its axis of rotation to a secondary axis of rotation or revolution impressed upon it, and he mentions the fact that this property is rarely described.

It was fully discussed in an elementary lecture given by Prof. Perry at the Royal Institution about fifteen years ago, and afterwards published in the Romance of Science Series under the title "Spinning Tops."

RECENT SPECTROHELIOGRAPH RESULTS.

IN a previous number of this Journal (vol. lxix. p. 609, 1904), under the heading of "A New Epoch in Solar Physics," I gave an account of the magnificent work that Prof. Hale had recently been accomplishing at the Yerkes Observatory with his latest form of spectroheliograph, the instrument being worked in conjunction with the great 42-inch Yerkes refractor, which forms an image of the sun seven inches in diameter.

In the present article it is proposed to give a brief description of another instrument based on the same principle, an account of which was published by M. Janssen, and to indicate some of the results which have been obtained with it. This instrument has been at work at the Solar Physics Observatory during the past year, and in a recent communication to the Royal Astronomical Society I gave a more full account of it, to which reference can be made for more detailed information than is here given.

FIG. 1.—The spectroheliograph, showing the general arrangement of the two slits, the collimating and camera tubes, the moving (upper) and fixed (lower) triangular frameworks.

It is not necessary in this place to refer at any length to the principle which underlies the construction of a spectroheliograph, since this was referred to in the article above mentioned. It will suffice here to say, therefore, that the pictures produced by this new method of solar research give us photographs of the sun in monochromatic light, or in rays of any particular wave-length that is desired. Thus if we require to study the distribution of hydrogen on or around the solar disc we employ a line in the spectrum of hydrogen, if calcium a calcium line, or iron an iron line.

There are, however, several methods of using the spectroheliograph. This instrument may either be employed in conjunction with a large equatorial, in which the solar image is moved across the primary slit by means of the declination motor which moves at the same time and rate the photographic plate; or the primary slit, and with it the whole spectroheliograph, may be moved across the image formed at the focus of the equatorial. The first method is that adopted at the Yerkes Observatory, and the second that at Potsdam.

There is a further method in which a stationary solar image is formed by means of a siderostat and lens, and the spectroheliograph is mounted horizontally and moved in an east and west direction across this fixed image. Such a mode of procedure is that employed at South Kensington.

The advantage of the last mentioned arrangement is that there is no limit to the size or weight of the spectroheliograph; the uniform motion required can be easily and efficiently secured, and lastly, this motion does not in any way affect the steadiness of the solar image under examination.

The South Kensington instrument was erected in the year 1903, but it was not until last year that satisfactory photographs were secured and routine work begun. This success was due to the use of a larger lens (12-inch) for throwing the solar image on the primary slit, the previous lens of 6 inches aperture not giving a sufficiently bright image.

In this curtailed description of the instrument reference of any length need only be made to the spectroheliograph proper. There is nothing particularly novel about the siderostat, except, perhaps, its more than usual size, the large mirror of 18 inches diameter, the two small motors for operating the slow motions in right ascension and declination, and a modified form of Russell control for regulating the speed of the driving clock. This instrument is

placed in a separate house the upper portion of which can be rolled back towards the north. Some distance due south of this, in another building, is the 12-inch Taylor photo-visual lens mounted on a concrete pillar, and still further south, and in the same building, is the spectroheliograph, also mounted on concrete pillars.

Wtih this arrangement the solar beam is thrown by the siderostat mirror continuously due south and in a horizontal direction; this beam then falls on the 12-inch lens, and the solar image in the focus of this lens is thrown on the primary slit plate of the spectroheliograph.

In order to analyse the solar image by allowing each portion of it to fall successively on the primary slit, the latter, and consequently the whole of the spectroheliograph, has to be moved horizontally in an east and west direction, a distance a little more than the diameter of the solar image (in this case 2½ inches). Further, this motion has to be extremely uniform.

The method adopted to accomplish both of these requirements is as follows:—A triangular iron framework (Fig. 1) is supported on three levelling screws on three concrete pillars. A second framework of the same size and material is placed on the first, but separated by steel balls free to roll between small steel plates fixed to each framework near the corners.

The longer side of this isosceles triangle is placed in a north and south direction. The direction of motion of the upper framework is restricted to an east and west line by means of a guide bar fixed to the lower framework; two small levers with rollers attached to the upper framework are pressed against this guide bar by means of small weights, thus ensuring the correct direction.

The actual motion of the upper framework is obtained by weights attached to one end of a steel strap the other end of which, after passing over a pulley mounted on an arm on the lower framework, is fixed to the western corner of the upper framework. This weight always tends to pull the upper framework towards the west, that is towards the right in Fig. 1.

The motion is controlled by a plunger projecting downwards from the upper framework operating a piston in a cylinder full of oil attached to the lower framework. The outlet valve can be so adjusted that any desired rate of motion can be obtained.

Owing to changes of temperature of the oil, different rates of movement can be obtained for any one reading of the micrometer head regulating the outlet valve. It is necessary, therefore, when making an exposure for a "disc" or "limb" picture to take the temperature of the oil into account. This is accomplished by employing a table, made from previous "runs," in which the valve setting can be directly read off from the temperature reading and the required length of exposure.

It is on the upper framework that the optical parts of the spectroheliograph are placed. These consist of a double tube carrying the two slits (Fig. 2) at the northern or siderostat end and the two lenses (4-inch) of equal focal length at the southern end. The dispersion is produced by a single prism of 60°, and a reflector is inserted in the system in order to make the total deviation of the beam 180°. Thus the part of the solar image which passes through the primary slit falls on the collimating lens, is reflected by the 6-inch mirror on to the prism, traverses the latter, and finally, after passing through the camera lens, is brought to a focus in the plane of the secondary slit in the form of a spectrum. By isolating any particular line in this spectrum by means of the secondary slit (Fig. 2) the solar image can be analysed in this wave-length.

For photographing the whole disc of the sun or its immediate surroundings with one exposure the lengths of the slits must be greater than the diameter of the solar image (2½ inches); in the present case they are 3 inches long. Further, owing to the fact that the lines in the spectrum are curved, the secondary slit jaws are curved to the same radius; this necessitates very accurate adjustment of the secondary slit on the line, and means are provided to facilitate such requirements.

In order to obtain a photographic record of the sun in monochromatic light, a fixed photographic plate is held by means of a wooden support as close to the secondary slit as possible (Fig. 2). In this way, as the primary slit moves over the stationary solar image, so the secondary slit traverses with equal speed the stationary photographic plate.

Up till now the secondary slit has usually been

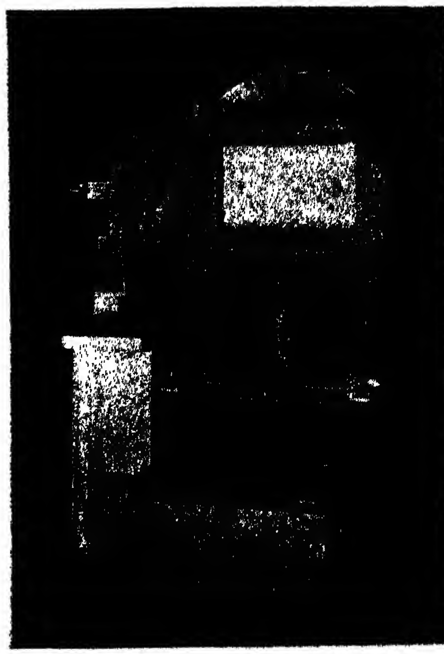

FIG. 2.—The primary slit is on the left and the secondary behind the plate carrier is seen on the right. This illustration shows also the metal disc in position for a "limb" exposure.

adjusted on the "K" line of calcium by eye estimation aided by a small watchmaker's lens, a check being made by taking a photograph of the spectrum, if possible with a sun-spot region, on the primary slit. On bright days this setting can be made with little difficulty, but during the late autumn, with a low sun, the "K" region of the spectrum is not easy to see, and the setting is in consequence very uncertain. A new method just brought into operation entirely eliminates this difficulty, for at a constant distance on the red side of the "K" line a small glass plate has been set with a cross engraved on its surface which can be adjusted on a known line in the more visible region of the spectrum. By bisecting a particular line with the cross the "K" line is adjusted on the slit jaw simultaneously.

The photographs taken during the past year have been of two kinds, the first to investigate the distribution and area of the calcium clouds, or flocculi as Prof. Hale has termed them, on the sun's disc, and

the second the distribution and forms of prominences round the limb. To obtain the latter, a metal disc just a little smaller than the solar image is placed close up to the primary slit plate (Fig. 2), and retained there by a metal wire fixed to a firm base; this disc is so adjusted that it is concentric with the solar image. While in use it becomes extremely hot, and it is therefore necessary that it be made of metal and riveted to the wire which supports it. These limb pictures, an example of which is given in Fig. 3, are of a composite nature in that after the exposure of the limb has been made the metal disc is removed from the primary slit, and a "disc" exposure is made on the same plate. It has been found by experience that a "limb" exposure requires about sixty times the time that is necessary for a "disc" exposure. Under very favourable conditions fifteen seconds is necessary for the latter and fifteen minutes for the former.

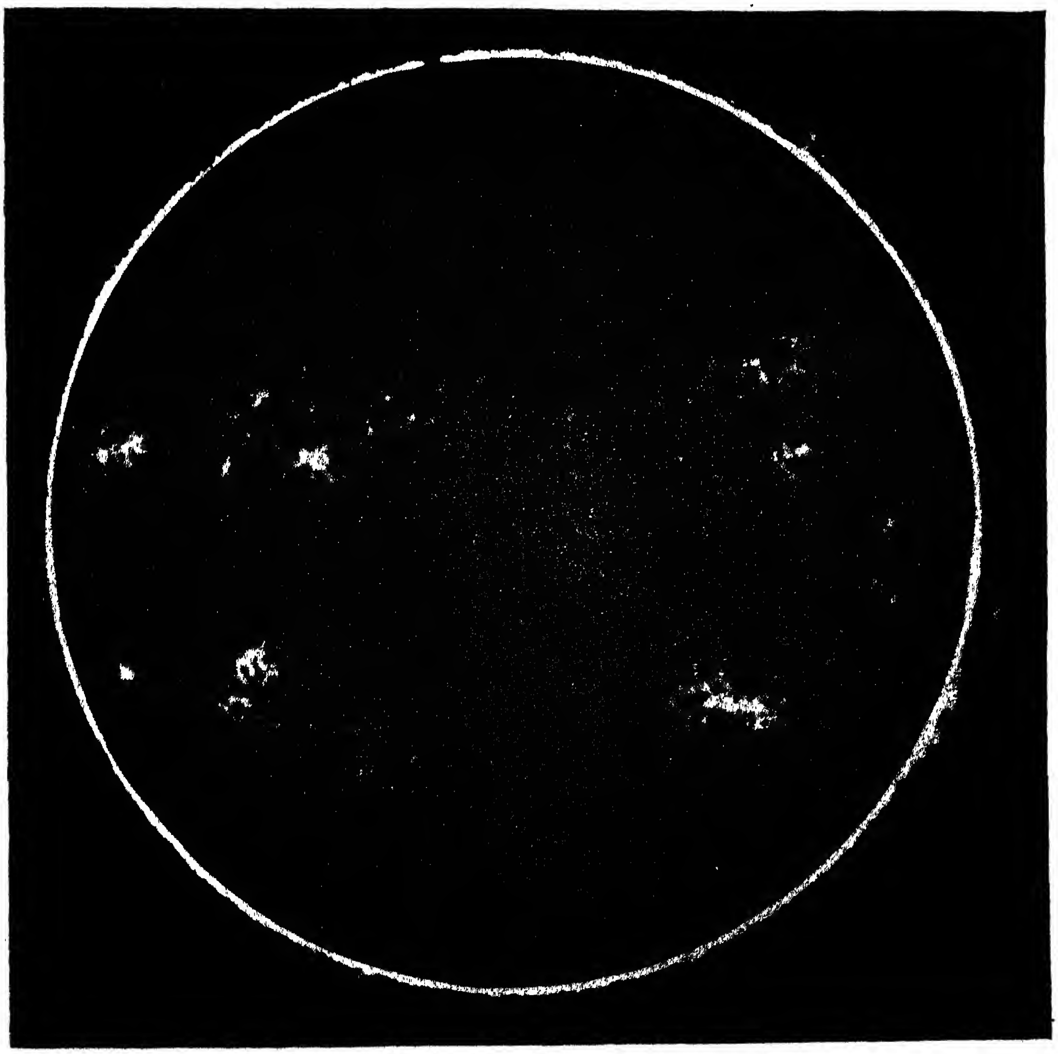

FIG. 3.—Limb and disc of sun in "K" light, July 19. Limb exposed rom 11h. 36m. to 11h. 52m. (interval 16m.); Disc exposed from 11h. 53m. 30s. to 11h. 53m. 48s. (interval 18s.). Enlarged nearly $2\frac{1}{2}$ times.

Without entering into too minute details, the following brief summary of the more salient facts derived from a general survey of the photographs taken during the past year may be given.

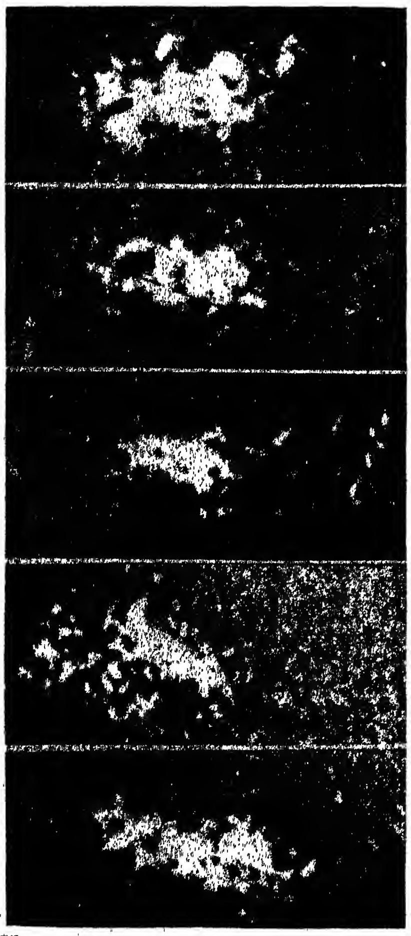
Dealing with the "disc" pictures in the first instance, all of them show a "mottling" of very definite character extending from the equator to the poles. Nearer the equatorial regions this mottling seems to become exaggerated in size in patches, some of the interspaces becoming filled up, giving rise to the prominent flocculi, many of which clearly indicate the mode of structure. Fig. 3 gives an idea of their appearance in the photographs. It will be seen that there are frequently long streaky bright portions springing apparently from a central nucleus and having subsidiary ramifications. A three-legged formation is a very common type of structure in many of the photographs.

These flocculi, in the first instance, exist alone, but

in some of them spots appear at a later stage. No spot has been photographed unaccompanied by a flocculus; in fact, the duration of a spot is only a brief interval in the life-history of a flocculus.

Another interesting subject of inquiry is the position of a spot in relation to the flocculus. Spots more generally make their appearance near the head of, or, in other words, precede the apparently trailing masses of the calcium clouds with respect to the solar rotation, which is from east to west. Some examples of these are given in Fig. 4. When there are two fairly large spots in one flocculus, the larger one nearly always precedes the smaller one.

The composite pictures (Fig. 3) showing the



1904

August 29

West East

FIG. 4.—Typical cases of spots situated in the front portions of flocculi.

"limb" and "disc" have also brought to light many interesting points which call for further inquiry. In the first place prominences both near the solar poles and equator give strong images in calcium light. Secondly, prominences, which occur nearer the solar poles than the flocculi, do not appear to disturb the regular mottling on the disc in these high latitudes.

Again, an intense flocculus, when on the limb, is not always accompanied by a large prominence. These two last mentioned facts seem to indicate that flocculi and prominences are not always interdependent phenomena.

On continuous fine days, when several photographs of the limb are secured, an opportunity is afforded of studying the changes in the form of large prominences after intervals of a few hours. Two examples of such changes are here illustrated and briefly described.

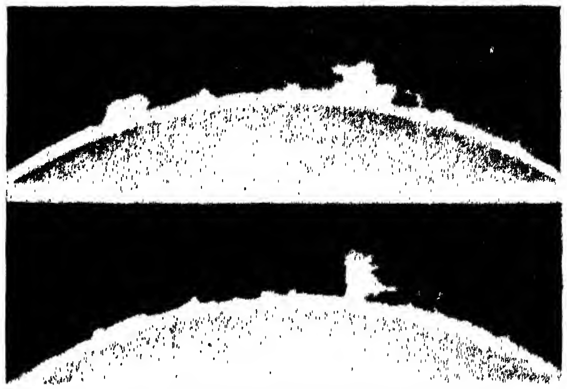

FIG. 5.—Showing changes in prominences after an interval of one hour. (Lower picture taken last.)

In Fig. 5 we have two photographs (only the portions of the limb indicating the particular region of the sun in question are shown) which were taken on July 14, 1904, at 11h. 8m. a.m. and 12h. 8m. p.m. respectively. It will be noticed that during this interval of about one hour a startling change has occurred to the largest prominence; not only has its height been considerably increased, but its form has entirely changed. The material radiating the calcium light seems to have been ejected from the chromosphere and then to have apparently met a strong current moving polewards (that is, from left to right in the figure) which has thrown this material in that particular direction. The change of height from about 50,000 miles to 60,000 miles in this interval corresponds to a velocity of nearly three miles a second.

Not less interesting is the apparent disappearance of the second large prominence in the figure situated on the left.

Another example of a change of form of an enormous prominence photographed on July 19 at 11h. 45m. a.m. and 3h. 59m. p.m. respectively is that shown in Fig. 6. This prominence was situated in the south-east quadrant. The approximate dimensions

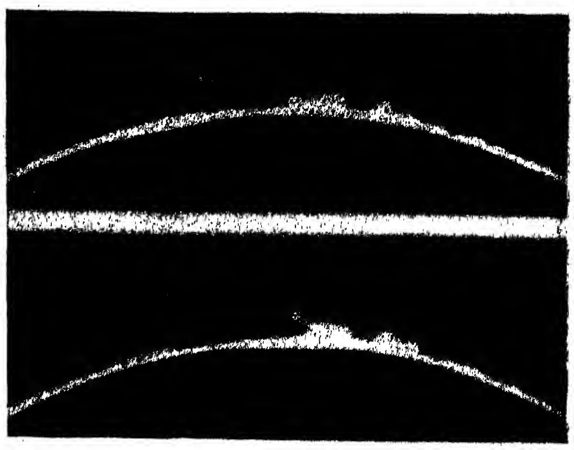

FIG. 6.—Two views of a large prominence taken with a four hours' interval between them. (Lower picture taken last.)

as deduced from measurements of the photographs were as follows :—

Time h. m.		Length in miles		Height in miles
11 45	...	192,000	...	55,000
3 59	...	216,000	...	60,000

When it is mentioned that our earth has a diameter a little less than 8000 miles, an idea of the magnitude of this solar disturbance can be roughly grasped.

An interesting point to notice further in the original is the apparent falling towards the limb of the material forming the highest part of the prominence in the lower picture.

Enough, perhaps, has now been written to give the reader an idea of the instrument at work, and a few deductions from the photographs obtained during the summer months of the past year.

When it is considered that the results described, and others of which no mention has been made, only apply to the photographs secured with the "K" line of calcium, and that other lines in the solar spectrum, such as hydrogen, iron, magnesium, &c., still remain to be examined, some notion of the vast field of work open to investigators becomes apparent.

To avoid too much duplication of work beyond what is absolutely necessary, steps should be taken as soon as possible to subdivide the labour. The past year has seen the formation of a representative body to undertake such a scheme, and it is hoped that more instruments will soon be erected and at work to cope with the large demand of facts relating to our sun rendered now possible by the pioneer work of Prof. Hale and M. Deslandres.

WILLIAM J. S. LOCKYER.

THE TEACHING VALUE OF MENAGERIES.[1]

SO far as the general public is concerned, there is always a very considerable danger lest menageries should be regarded merely as places of amusement and curiosity, and that their great value as teachers of zoology should be more or less completely ignored. The main object of the volume before us appears to be to emphasise the teaching value of institutions of this nature, and to show what admirable schools for acquiring the rudiments of practical zoology lie ready to our hand, if only we will take advantage of our opportunities; in other words, we have nature-teaching of a unique description awaiting our attention. Mr. Beddard treats, indeed, his subject almost exclusively from this point of view, so that his volume forms, in great degree, a sketchy kind of text-book of vertebrate zoology, illustrated by a number of first-class photographs and drawings of the animals under discussion. Such a mode of treatment necessarily prevents the inclusion of any great amount of matter that is really new in his work, and from one point of view it is a matter for regret that the author, with his long experience of the establishment in the Regent's Park, has not seen his way to give us more information with regard to the behaviour and life-history of animals in menageries. One point in this connection on which information is sadly lacking is the duration of life of animals in menageries, and the periods during which individuals of long-lived species have survived in captivity. So far as we have seen, information on this latter point is given only in two cases, namely, in that of the polar bear and that of the pelican. Possibly, however, the author may have in view a companion volume, in which these phases will form the leading theme; and if so, we feel sure that it will supply a marked want.

FIG. 1.—Flamingoes in the Regent's Park. From Beddard's "Natural History in Zoological Gardens."

Restricting, and very wisely so, his volume to the vertebrata, the author commences with a general sketch of the leading features of that group, and then takes in systematic order the various representatives selected for description. Mammals accordingly come first; and it is not out of place to mention that Mr. Beddard directs attention to the fact that a good popular name for this group is still a desideratum. In the case of both mammals and birds, the species taken as examples of different types are in the main well selected, and in nearly every instance the illustrations are almost everything that can be desired. As one of the best, among those reproduced from photographs, we have chosen the group of flamingoes, taken in the gardens, to set before our readers.

[1] "Natural History in Zoological Gardens; being some Account of Vertebrated Animals, with Special Reference to those usually seen in the Zoological Society's Gardens in London and Similar Institutions." By F. E. Beddard. Pp. x+310; illustrated. (London: Archibald Constable and Co., Ltd., 1905.) Price 6s. net.

Typographical errors appear to be comparatively few. The meaning of the last sentence on p. 22 is, however, obscured by the misplacing of the word "much"; while on p. 125 we have *Suiae* for *Suidae*, and on p. 149 Australia for Australian. As regards other matters for criticism, it may be pointed out that the author admits that the term aurochs properly belongs to the extinct wild ox, and it is therefore not easy to see why he applies it to the bison in the plate of that animal. In the section on the wild ass (p. 60), the non-scientific reader will probably find it difficult to ascertain the proper name and the number of races of the Asiatic representative of that group; while the sportsman will gasp with astonishment when told (p. 63) that this animal may be ridden down by an expert horseman after a run of five-and-twenty miles (or does the author mean minutes?). On p. 139 the Tasmanian devil, under the synonym of the ursine dasyure, is made to do duty for two species. Finally, the palæontologist is likely to be staggered by the suggestion (p. 185) that the horn of the American birds commonly known as screamers is a direct inheritance from a dinosaurian ancestor.

Throughout, Mr. Beddard has made his book readable and mildly interesting; and it is especially satisfactory to find that he is conservative as regards the scientific names of the animals he discusses, and is, moreover, sparing in the use of such of these names as he selects to designate the various species. The book should form a valuable companion during a visit to the gardens in the Regent's Park, and likewise an excellent work of reference to those who really desire to learn something from visits of this nature.

R. L.

SCIENCE AT THE ROYAL ACADEMY BANQUET.

AMONG the guests of the Royal Academy of Arts, at the anniversary banquet on Saturday last, were eminent representatives of many branches of science. The president of the Academy, Sir E. J. Poynter, presided; and the Prince of Wales responded to the loyal toast proposed by the chairman. Sir E. Seymour having replied for the Navy and the Duke of Connaught for the Army, the president proposed the toast of "Science," the domain of which, he remarked, appeals to innumerable interests from its utilitarian side, and in its higher aspects deals with matters which, while they transcend the imagination with their speculative possibilities, require for their verification the utmost capacity of the intellect for exactitude and minuteness of research. Sir William Huggins, president of the Royal Society, replied to the toast in the following speech, which we take from the *Times* report of the banquet:—

I rise, as representing the Royal Society, to acknowledge the toast of science, so cordially honoured by her younger sister, the Royal Academy. I say sister, because art and science have in common the same object of worship and study—nature, in her varying moods and aspects; art "to exalt the forms of nature," science "to enlarge her powers." More than this, for to be accepted of nature, to be true artists or true men of science, both must possess an intuitive and profound insight into nature. The fine paintings which surround us are not mere transcripts of nature, but created visions of nature, revealing to the common eye the cryptic poetry and prose visible only to the second sight of the true artist—

"... a painter gazing at a face
Divinely through all hindrance finds the man behind it."

As truly, the man of science must be a seer, endowed with the open eye and power of imagination. At this point the sisters part company. The muse of art fixes on the canvas a momentary aspect of nature, or of the human face divine. The muse of science strains her eyes to see what is behind the outward show, her quest is for the why and wherefore of nature's changes. But science is more than a presiding muse; she is in very deed a great beneficent power imminent in the lives of her votaries, a power such as was feebly foreshadowed in the tales of folk-lore by the Queen of the Good Fairies, richly rewarding by enchantment with all good things those who made her their friend. The seven-league boots and the magic steeds were but poor anticipations of the gifts of science —the railway, the motor, and the turbine-driven vessel. The enchantment of gold, jewels, feasts, and palaces are more than realised by the boundless resources which science places at man's disposal. Science, indeed, brings back the age of Methuselah. Even literally life is prolonged by increased power over disease. True life is not measured by the passing of the suns, but by the sum of our activities; not by the falling sands of the hour-glass, but by the living pulses of the mind. The flying train, the flashing of intelligence, night turned into day, and the thousand and one appliances of machinery crowd into one year a fulness of life which was possible to our fathers only, if at all, in many years. How great, then, would be the gifts of science to the nation in return for full national recognition—by placing science on an equality with the humanities in our universities and public schools, and by the endowment of laboratories worthy of the nation! With science nationally honoured, our armies and our ships could know no defeat, our machinery and our manufactures no rivalry in the world's markets, our every undertaking must prosper. Shall we then remain in deadly apathy and take no steps to have it so?

NOTES.

ON Sunday, the President of the French Republic entertained the King at the Elysée at a dinner party, at which 120 guests were present. The guests included distinguished authors, artists, musicians, and other representatives of intellectual activity, almost exclusively members of the Institute of France. By inviting leaders of literature, art, and science to meet the King, graceful recognition was given of the high place occupied by the muses in the polity of the Republic. In the days when sheer muscular force was the mainstay of a nation, bodily strength and prowess were rightly regarded as recommendations for Court favours; but now that brain-power instead of muscle determines the rate of national progress, the State that desires to advance must foster all the intellectual forces it possesses. This principle is well understood in France, and is also clearly recognised in Germany, where every man who makes notable contributions to knowledge of any kind, assists industrial progress, or creates works of distinguished merit, whatever they may be, is sure to receive personal encouragement from the Emperor. The presence of these leaders of thought is a striking characteristic of the German Court; while, on the other hand, their absence, and the overpowering influence of military interests, are distinguishing features of Russian, and, let us add, of British Court functions.

ON many occasions reference has been made in these columns to the excellent object lesson of the intimate connection between a scientifically organised system of education and national prosperity afforded by the success which has in recent years attended Japanese enterprise. It is gratifying to find that this insistence on our part is, in view of affairs in the Far East, now being echoed by our contemporaries. Commenting upon the account of its Tokio correspondent of the battle of Mukden, the *Times*, in a leader in the issue of April 25, remarked:—"We have before us evidence of national education in its highest and most complete manifestation—education such as we in this country have hardly begun to conceive. We have co-

ordinated intelligence at its best, fortified by an invincible *moral*, and employing a physical education capable of carrying out all its behests. We see these things not merely producing a small *corps d'élite* insignificant in comparison with the mass of the nation, but turning out half a million of men with brain power adequate for their direction." When it is remembered that Japan has established and perfected its system of education in the years since the passing of our first Elementary Education Act in 1870, it is easy to appreciate how profound and speedy can be the effect of an earnest and sustained effort on the part of the Government of a nation to develop its educational resources. There is hope that now our great newspapers are advocating the paramount claims of higher education and science we may see both more generously treated by the Government of this country.

THE inactivity shown by our statesmen in matters concerning the preservation of our ancient monuments compares very unfavourably with the measures taken in other countries to cherish their structures of antiquity. A timely article in the April number of the *Quarterly Review* directs attention to several cases of vandalism to show the precarious tenure on which this country holds so many of its artistic and historical treasures. Here we are almost devoid of the official and semi-official machinery which is actively engaged abroad. France and Austria have State-appointed commissions which exercise a general supervision over historical and artistic monuments, and see to their preservation and proper repair. The French list of structures regarded as of unmistakable national value contains about 2200 monuments, of which 318 are prehistoric in the form of dolmens or cromlechs. The care of monuments in all the German States is in the hands of official custodians or monument commissions, who are responsible to the Ministers of Public Instruction or of the Interior. The minor States of Europe exhibit a similar official interest in historical monuments. In our own country, however, only tentative efforts have been made at arrangements which on the Continent are in full working order. So far as any expenditure is concerned, the Ancient Monuments Acts are almost a dead letter. The indifference of the Government to the whole matter is sufficiently indicated by the fact that since the death of the inspector of ancient monuments, General Pitt-Rivers, in 1900, no successor has been appointed to the post, although no emoluments are attached to it. It seems impossible to get our so-called statesmen to see that unless the State shows active interest in the preservation of our ancient monuments, many of our national assets of the highest historical value are doomed to destruction. The public and public bodies would soon learn to prize such monuments if the Government would take steps to show that these structures are of national importance.

MR. E. T. NEWTON, F.R.S., palæontologist to the Geological Survey, retired on May 4 after a distinguished service extending over forty years. In 1865 he joined the Geological Survey as assistant naturalist under Prof. Huxley, while Murchison was director-general; and when Huxley severed his connection with the Museum of Practical Geology, he worked under the late Robert Etheridge until 1881. On Mr. Etheridge's transfer to the British Museum, Mr. George Sharman and Mr. E. T. Newton were appointed joint palæontologists to the Geological Survey, and on Mr. Sharman's retirement in 1897 Mr. Newton remained as chief of the palæontological department. The loss of his great experience and knowledge on all branches of palæontology, to say nothing of the personal loss, will be widely felt in the museum at Jermyn Street by the officers and by the visitors who come for assistance in the study of fossils. It is satisfactory to learn that Dr. F. L. Kitchin has been appointed to succeed Mr. Newton; he received his palæontological training under Zittel, and joined the staff of the Geological Survey in 1898. He has published important monographs on fossil Invertebrata in the "Palæontologia Indica."

MR. JOHN GAVEY, C.B., engineer-in-chief to the Post Office, has been nominated for election as president for 1905–6 of the Institution of Electrical Engineers.

NEWS has just reached this country that Dr. J. E. Dutton died at Kosongo, in the Congo, on February 27, while actively engaged in the investigation of trypanosomiasis and tick fever.

THE Paris Natural History Museum has accepted a bequest made by M. Emmanuel Drake del Castillo consisting of a herbarium, a botanical library, and a sum of 25,000 francs.

PROF. HANS MEYER, of the University of Vienna, we learn from *Science*, has accepted the invitation to deliver the Herter lectures at Johns Hopkins University on October 5 and 6. His subject will be "The Physiological Results of Pharmacological Research."

IT is announced that the New Mexico legislature has passed a law authorising a geological survey of the State; the sum of 1200*l*. has been voted for the purpose, and is to be expended under the direction of the New Mexico School of Mines at Socorro.

PROF. W. KÖNIG, of Greifswald, has been appointed ordinary professor and director of the physical laboratory at Giessen; Prof. M. Disteli, of Strassburg, professor of mathematics at Dresden; and Dr. Ernest Orloch professor at the National Physical Laboratory at Charlottenburg.

PROF. H. M. HOWE, professor of metallurgy at Columbia University, Bessemer medallist of the Iron and Steel Institute, has been elected foreign correspondent of the Paris Society for the Encouragement of Industry to succeed Sir Lowthian Bell. The other four recipients of this honour are Cannizzaro, Mendeléeff, Solvay, and Sir Henry Roscoe.

MR. J. H. HAMMOND has given 1000*l*. to establish a mining and metallurgical library at San Francisco. The State Mining Bureau already possesses an extensive library, but, for want of funds, it has not been possible to add new books during the past ten years. The new library is to be placed in the rooms of the Mining Bureau, but as a separate unit. Three trustees are to select the books.

THE President of the Board of Agriculture and Fisheries has appointed a departmental committee to inquire, by means of experimental investigation and otherwise, into the pathology and etiology of epizootic abortion, and to consider whether any, and, if so, what, preventive and remedial measures may with advantage be adopted with respect to that disease. The chairman of the committee is Prof. J. MacFadyean, principal of the Royal Veterinary College.

THE Baly medal, given every alternate year on the recommendation of the president and council of the Royal College of Physicians of London for distinguished work in the science of physiology, especially during the two years immediately preceding the award, has been awarded to Prof. Pawloff, of St. Petersburg. The Bisset Hawkins

gold medal for 1905, given triennially for work deserving special recognition as advancing sanitary science or promoting public health, has been awarded to Sir Patrick Manson, K.C.M.G.

A DECIDED earthquake shock was felt in the Vale of Llangollen, North Wales, about 1.40 a.m. on May 1. The disturbance lasted about four seconds, and was accompanied by loud rumbling sounds. The river Dee, which runs through the district, rose several feet during the night.

THE Paris correspondent of the *Times* reports that earthquake shocks were experienced at about 2 a.m. on April 29 over the whole of the Jura, the Rhone valley between Lyons and Valence, and the eastern portion of the *Central Massive*. All the shocks appear to have occurred simultaneously, and were accompanied by sudden and violent squalls, as well as by rumblings like distant thunder. An earthquake shock, lasting eight seconds, was recorded also at Chamonix. Subsequently the shocks recurred, though in a mitigated degree. At this place a new spring suddenly gushed from the ground as the result of the seismic disturbance, and the waters of the river Arve were swollen in consequence. The shock was felt at 2.45 a.m. at Turin and Domodossola. The seismographs at the observatories of Pavia, Padua, Ferrara, Modena, Ischia, and other towns also recorded disturbances. At Heidelberg Observatory the seismograph registered a decided earthquake of short duration at 2.49 a.m.

ATTENTION was recently directed in these notes (vol. lxxi. p. 492) to a statement made in the *Times* that the Tower of Galileo on the hill of Arcetri, near Florence, has been practically destroyed in the course of recent building operations. Prof. A. Ricco, having been led by our note to make a special inquiry at Florence, now writes to point out that the so-called Torre del Gallo cannot in any way be considered as associated with the name of Galileo. Such an association was first suggested comparatively recently and purely gratuitously by the late proprietor of the tower, but no evidence in support of it can be traced either in the numerous letters or writings of Galileo. This was clearly pointed out by Gebler in 1878 in an article in the *Deutsche Rundschau*, and the most recent examination of Galileo's writings made on the occasion of the publication of the "national edition" of his works has given support to the same opinion. It may perhaps be surmised that a confusion of names has occurred, Torre del Gallo, literally the Cock's Tower, being wrongly regarded as a corruption of Torre di Galileo.

IN one of his recent articles on Stonehenge (vol. lxxi. p. 391, February 23) Sir Norman Lockyer referred to the interesting fact, pointed out to him by Colonel Johnston, director of the Ordnance Survey, that the solstitial line in 1680 B.C. passes through not only the present centre of Stonehenge, but also through Sidbury Hill to the north-east, and the earthworks at Grovely Castle and Castle Ditches to the south-west. This continuation of the solstitial line from Stonehenge to other ancient structures is of great interest; but an even more remarkable relation found by Colonel Johnston is that Stonehenge, Old Sarum, and Grovely Castle occupy the points of an equilateral triangle each side of which is exactly six miles in length. A very definite connection is thus shown to exist between the various primitive works in the neighbourhood of Stonehenge. We notice that Mr. J. H. Spencer describes these relationships in an article in the April number of the *Antiquary*, but he does not mention that the credit of the discovery of the connecting lines between the various monuments belongs to Colonel Johnston.

WE learn from the *Journal of the Society of Arts* that funds have been placed at the disposal of the council of the Society of Dyers and Colourists for distribution in the form of prizes for the solution of technical problems. The following prizes are now offered:—(1) 20*l*. for a satisfactory systematic tabulation of the reactions of dyestuffs on the fibre, and a comprehensive scheme for their identification on dyed fabrics; (2) 10*l*. for a trustworthy method of distinguishing between unmercerised and mercerised cotton of various qualities, and for the estimation of the degree of mercerisation without reference to lustre; (3) 20*l*. for a full investigation of the causes of the tendering of cotton dyed with sulphide blacks, and the best means of preventing such tendering; (4) 20*l*. for a satisfactory standardisation of the strength and elasticity of cotton yarns of various qualities and twists in the grey and bleached conditions; (5) 20*l*. for a full investigation of the average degree of tendering brought about in cotton yarn of various qualities by—(*a*) cross dyeing with acid colours; (*b*) dyeing aniline black; and (*c*) various other dyeing processes, with the object of fixing standards for the trade. Further information can be obtained from the hon. secretary, Mr. E. T. Holdsworth, Westholme, Great Horton, Bradford.

SATISFACTORY progress and general prosperity form the key-note of the report of the Zoological Gardens at Gizeh for the past year. The report is illustrated by the reproduction of a most interesting photograph of an aard-vark, or ant-bear, slightly marred by the effect of a shadow by the side of the nose.

IN a communication published in the *Anales of the Buenos Aires Museum* (vol. xii. pp. 1-64), Dr. F. Ameghino gives reasons for concluding that the single facet by which the astragalus of marsupials articulates inferiorly with the calcaneum is a specialised feature, derived from the more common type in which there are two such facets.

THE April issue of the *Proceedings of the Royal Irish Academy* is devoted to a list of Irish Cœlenterata, inclusive of the Ctenophora, by Miss Stephens. The list includes about 250 species, but since the north-west coast of Ireland has not yet been thoroughly worked, it cannot be regarded as complete.

Museum News is the title of a periodical issued by the Brooklyn (N.Y.) Institute of Arts and Sciences to replace the *Children's Museum News*, and intended to deal with matters connected with both the Central and the Children's Museum in that city. Special attention will be devoted to informing the public with regard to new exhibits and additions to the collections.

ACCORDING to its seventy-first report, Bootham School (York) is making a vigorous push in the direction of encouraging the study of natural science, and the natural history club has entered a period of renewed life and vigour. The report is illustrated with reproductions from two excellent photographs, one showing the nest and eggs of a black-headed gull, and the other the same eggs in the process of hatching.

THE seals frequenting Killala Bay and the Moy Estuary in Mayo, form the subject of an article by Mr. R. Warren in the April *Zoologist*. Both the common and the grey seal frequent and breed in this district, the young being apparently born in most cases in caverns difficult of access

The largest grey seal ever killed weighed 560 lb., but specimens scaling 740 lb. and 770 lb. are recorded from the Farne Islands, on the Northumberland coast.

"DIE SOGENNANTEN RIECHSTÄBCHEN DER CLADOCEREN" is the title of a paper in vol. xii. of *Ploner Forschungsberichte*, in which the author, Mr. D. J. Scourfield, of Leytonstone, discusses the function of the so-called olfactory setæ in this group of minute crustaceans. From the stronger and more numerous development of these bristles in the males, it is inferred that their sensory functions are more acute in this sex than in the females. As regards their probable function, the author is of opinion that while they are largely concerned in the perception of taste, yet that they may also serve in the recognition of other senses which may be as far removed from taste as is the latter from hearing.

THE *Journal of Hygiene* for April (v., No. 2) contains a number of interesting and important papers. Dr. Petrie discusses the relationship of the pseudo-diphtheria and diphtheria bacilli, and Dr. Boycott the relative seasonal prevalence of these two organisms. Dr. Petrie also describes trypanosomes observed in rabbits, moles, and certain birds. Dr. Savage, as the result of experiments made to ascertain the degree of sewage pollution of tidal waters, considers that mud samples yield more trustworthy evidence of the degree of contamination than either water or oyster samples. Other papers are by Dr. Hamilton Wright on preventive measures against beri-beri, Drs. Newsholme and Stevenson, and Dr. Hayward on statistical methods applied to birth-rates and life tables, and Dr. Mackie on a handy method of determining the amount of carbonic acid in air.

PART i. of the reports of the commission appointed for the investigation of Mediterranean fever under the supervision of the advisory committee of the Royal Society has just been issued. The first two reports, by Major Horrocks, R.A.M.C., deal with the problem of the saprophytic existence of the causative organism (the *M. melitensis*) outside the human body. It is found that the organism will retain its vitality in sterilised tap water for thirty-seven days, in dry soil for forty-three days, and in moist soil for seventy-two days. The same observer was able to isolate the micrococcus from the urine, but not from the fæces, sweat or breath of patients. A series of experiments was instituted which showed that the micrococcus is absorbed by, and gives rise to the disease in, monkeys exposed to dust, or given food containing it. Staff-Surgeon Gilmour, R.N., and Dr. Zammit detail experiments on the isolation of the *M. melitensis* from the blood, and Staff-Surgeon Shaw, R.N., writes on the same subject and on experimental work in relation to animals.

AN interesting article on polished stone axes in history until the nineteenth century, by Dr. Marcel Baudouin and Lionel Bonnemère, will be found in the *Bulletin de la Société d'Anthropologie de Paris* (5e. sér., tome v., p. 496). Examples are given of their use at the present day as charms against lightning, storm, and other evils, and also they are credited with therapeutic efficacy. The βαίτυλος of the Greeks was a polished stone implement; from classical times onwards these stones were supposed to have fallen from heaven, and at the present day this belief is current from western Europe to Malaysia.

VARIOUS folk-tales and other items of folklore will be found in the *Journal of the Asiatic Society of Bengal*; in vol. lxx., part iii., p. 99, Mr. S. C. Mitra records a new accumulation-droll or cumulative folk-tale from Bihar; in vol. lxxi., part iii., p. 4, in the same *Journal*, Mr. H. P. Shastri describes a form of tree worship at Naihati; a female deity is supposed to reside in a date palm, when clods of earth are thrown at the tree as offerings to her, she at once pacifies children crying at the home of the devotee. Ten years later the author re-visited the spot, and found that sweets were then offered as well, that various other boons were prayed for, and a myth had grown up about the tree. The marriage customs of the Khonds are described by Mr. J. E. F. Pereira, from which it appears that they are gradually Hinduising their customs.

THE ideal forestry college forms the subject of an article in the *Indian Forester* (February); the suggestions made are based upon a selection of the advantages observed at various institutions, all of which, it is hardly necessary to state, lie outside the British Isles. College gardens and forests are mentioned as the most important adjuncts to laboratories and museums, and in these particulars the forestry school at Tharandt, Saxony, is well provided. In the matter of getting wider experience than can be obtained in the college forests, the students of the St. Petersburg Institute have the advantage of inspecting and completing a final course in some of the great forest areas of Russia.

JUDGING from the account by Mr. J. W. White published in vol. xxii., part iv., of the *Transactions and Proceedings of the Botanical Society of Edinburgh*, the Balearic Islands offer many attractions to the botanist who is contemplating a holiday. Not only do the islands lie outside the general track of tourists, but the flora is unusually rich, and a considerable number of the plants are endemic or confined to one of the neighbouring countries. Amongst the rarer curiosities a fragile vetchling, *Vicia bifoliata*, *Lepidium Carrerasii*, and a curious little shrubby *Daphne velloeoides* were obtained in Minorca, and in Majorca *Pimpinella Bicknelli*, which grows in splendid isolation, and a delicate rock-sheltered labiate, *Salvia Vigineuxii*, were discovered.

A RECORD of the progress of the *Albatross* Expedition to the eastern Pacific is given in a letter from Prof. Alexander Agassiz dated January 6 (*Amer. Journ. Science*, April). The influence of the Humboldt current on the marine life west of Callao was investigated. As far as 800 miles from the mainland, it affected both the surface and bottom fauna. Towards Easter Island, the surface fauna first became less abundant, and at a distance of from 1200 to 1400 miles from South America the trawl hauls were absolutely barren. The bottom of the greater part of the line was covered with manganese nodules on which were found attached a few siliceous sponges, an occasional ophiuran, and a few brachiopods and worm-tubes. The pelagic and intermediate fauna from Easter Island to 12° south latitude, in the direction of the Galapagos, was very poor, and indicated that the region was to the westward of the great Humboldt current. Beyond this limit the marine fauna was again rich and abundant, and great changes were noted in the temperature of the water between 50 and 300 fathoms. Soundings made eastward of the Galapagos and Easter Island indicate a gradual deepening of the ocean bed towards the Continent, as observed during the *Challenger* Expedition. On Easter Island some time was spent in examining the prehistoric monuments and the great quarries from which colossal images had been cut. Sculptured rocks were noted, and it was remarked that some of the cyclopean stones used in the ancient buildings exhibited excellent workmanship.

Geological and petrographical researches on the northern Urals have for some years been carried on by Prof. Louis Duparc and Dr. Francis Pearce. Their latest work (*Mém. Soc. de Physique et d'Hist. nat. de Génève,* xxxiv., fasc. v.) embraces a description of the eruptive rocks of the chain of Tilaï-Kanjakowsky-Cérébriansky, in the Government of Perm. This range is composed of basic igneous rocks, of pyroxenites passing into koswites, which form the principal axis of the chain, with bordering gabbros elsewhere prominent; there are diorites, norites which are intercalated locally in both gabbros and pyroxenites, and dunites which are massive in places and also send veins into the gabbros and pyroxenites; and there are other eruptive rocks. All these are described in considerable detail and illustrated. Continuing their observations eastwards, the authors describe the quartzites and crystalline conglomerates of Aslianka and of Tépil, with, in the latter region, Devonian strata and various igneous rocks; and finally they deal with the crystalline schists and intrusive rocks of Koswinsky-Katéchersky-Tilaï. The memoir is illustrated by pictorial views of the topographic features, by longitudinal sections, and by microscopic sections of the rocks.

The report of the observatory department of the National Physical Laboratory for the year 1904 shows, as usual, a large amount of useful work; it is published separately, as appealing to a different class of workers from that interested in the engineering and physics departments. The work of the observatory deals with magnetic, meteorological, and seismological observations (separately), experiments and researches, verification of instruments and watches (separately), and miscellaneous commissions for inland, colonial, and foreign institutions, &c. It is observed that the electric trams have interfered with part of the magnetic work; the mean declination for the year was 16° 37′·9 W. The tabulations and automatic records of the meteorological observations are sent to the Meteorological Office for publication in detail; the Kew report contains monthly and yearly summaries of the results. The seismological observations are published in the report of the British Association; the largest disturbance recorded during the year took place on April 4, when the maximum amplitude exceeded 17 mm. The verification of instruments, exclusive of watches and chronometers, amounted to 25,797, of which 15,903 were clinical thermometers.

During a thunderstorm it has often been noticed that some flashes of lightning appear to "flicker," while others seem to leave a glow in their paths which lasts a second or two before entirely disappearing. In the first case the apparent trembling of the light is due to the fact that the observer is actually watching the passage of more than one flash following the same route. In multiple or intermittent lightning flashes there are sometimes as many as five or six separate flashes in a very brief interval of time, and the impression on the retina is an apparent flickering of a single flash. In the *Comptes rendus* (April 10) M. Em. Touchet directs attention to those particular flashes which leave a glow in their wake, and gives an illustration of a photograph of one he secured with a moving camera on April 12 of last year. The object of the communication is to point out that this glow is attributable to the incandescence of the air; but it seems to us that this is a fact already very well known. In photographing very bright lightning flashes with movable cameras it is a very common occurrence to get trails on the plate of the brighter portions of the flash, and if the plate and lens be very rapid it should be the rule rather than the exception. There are numerous examples of flashes which have been photographed showing this peculiarity, and it is a simple matter to differentiate between those due to multiplicity and those due to the incandescent air resulting from the original flash. Anyone interested in this question will find some typical photographs published by L. Weber (*Sitz. d. k. Preuss. Akad. d. Wiss.*, vol. xxxviii., 1889), Ladislaus von Szalay (*Met. Zeit.*, vol. xxxviii., 1903, p. 341), and B. Walter (*Jahrbuch d. Hamburgischen Wiss. Anstalten*, vol. xx., 1903). As M. Touchet refers to Dr. Hoffert's paper on intermittent lightning-flashes (*Phil. Mag.*, August, 1889), reference is there made to "streaks of light, showing that a very considerable residual illumination remains between the discharges," which indicates that the writer was quite familiar with the incandescence of the air due to the flash and its effect on the photographic film.

An installation for the production of high-tension electricity, on view at Messrs. Isenthal and Co.'s, 85 Mortimer Street, Cavendish Square, W., has been examined by a representative of Nature. The original source of the energy is an ordinary uni-directional current, and an important feature of the apparatus is a commutator which does away with the necessity for an interrupter. In the main circuit is a condenser of very large capacity, and the commutator breaks the circuit when the condenser is charged, so that no sparking is produced. The condenser employed is not large, and owes its compactness to the use of thin layers of aluminium oxide, prepared electrolytically, as the dielectric. The commutator has the appearance of a piece of engineering work, and should not require much attention. Oscillatory currents, with a frequency of about a thousand per second, are set up in the primary of an induction coil, and it is claimed that the impulses in the secondary are much stronger in one direction than in the other. The apparatus is also intended for the production of alternating currents, and some very interesting experiments are shown. An alternating current is sent through the coil of an electromagnet, the core being vertical; a sheet of paper is placed over the upper pole, and on the paper is scattered some iron dust (not filings); the dust forms itself into little spiked heaps which move and dance about. When the paper and iron dust are removed, and the forehead is placed near the pole of the magnet, the light of the room appears to fluctuate in intensity.

Messrs. A. Brown and Sons, Ltd., will publish during this month a work by Mr. J. R. Mortimer entitled "Forty Years' Researches in British and Saxon Burial Mounds of East Yorkshire, including Romano-British Discoveries and a Description of the Ancient Entrenchments on a Section of the Yorkshire Wolds."

The report of the council of the Hampstead Scientific Society and the proceedings for 1904 have been received. Fifty-six new members were elected during the year, and the number of members is now 333. The number of meetings held in 1904 was thirty-three, and in addition there were four Christmas lectures to children and a course of six lectures on nature-study. Among lectures delivered at general meetings of the society may be mentioned one by Prof. S. P. Thompson, F.R.S., on Japanese magic mirrors, and one by Prof. W. Boyd Dawkins, F.R.S., on the incoming of the Brythons into Britain.

Messrs. S. Rentell and Co., Ltd., have published a fifth edition of "The Telegraphists' Guide to the Departmental and City and Guilds Examinations in Telegraphy," by Messrs. James Bell and S. Wilson. The contents have

been revised thoroughly, the chapters re-arranged, and much fresh matter introduced. The extra pages supply a description of Wheatstone's ABC instrument, a more detailed reference to batteries, single-needle working, duplex and Wheatstone automatic systems, repeaters, test cases, concentrator switch, wireless telegraphy, and other subjects.

No. 5 of the *Central*—the magazine of the Central Technical College—is very good, and may be regarded as even constituting an advance on its predecessors. It contains an account by Mr. R. Freeman of the design and construction of the steel-work of the bridge over the Zambezi at Victoria Falls, a continuation of the series of articles by Prof. Armstrong on the mechanism of combustion, and a description of the Klingenberg carriage switchgear by Mr. J. D. Griffin. The magazine is well and copiously illustrated.

WE have received from Mr. Geoffrey Martin a copy of a paper on the theory of solution, published in the *Journal of Physical Chemistry* (vol. ix. p. 149), giving a detailed account of views already briefly stated in a letter to NATURE (vol. lxx. p. 531). An attempt is made to explain the fundamental facts that for all substances there is a limit of solubility in each solvent, that the solubility increases as a rule with the temperature, and that molecules often dissociate on passing into solution.

AMONG the popular science lectures to be delivered at the Royal Victoria Hall, Waterloo Bridge Road, during May are the following:—May 9, fishes old and new, Dr. Smith Woodward, F.R.S.; May 23, some summits of the lost continent Atlantis, Mr. H. Ling

OUR ASTRONOMICAL COLUMN.

DISCOVERY OF A TENTH SATELLITE TO SATURN.—A telegram from the Kiel Centralstelle announces the discovery of a tenth satellite to Saturn by Prof. W. H. Pickering, who, it will be remembered, also discovered Phœbe, the ninth satellite.

The newly discovered satellite is very faint, being reported as three magnitudes fainter than Hyperion, the seventh satellite, which has a magnitude of about 17; its period is given as 21 days, and its orbital motion is direct.

THE ALLEGED IDENTITY OF COMETS "BROOKS 1889" AND LEXELL.—An abstract of a paper by Dr. Charles L. Poor, wherein he discusses the identity of Brooks's 1889 comet with the object known as Lexell's comet, is given in No. 4, vol. xiii., of *Popular Astronomy*. After mentioning the discovery and subsequent history of each body, he discusses the various perturbations to which each has been subjected, and then gives the results obtained from a re-computation of the orbit of Brooks's comet, using the observational data secured during the re-appearance of 1903. Finally, he arrives at the conclusion that the objects are not identical, although further evidence will be necessary before the question can be settled definitely.

ANCIENT DRAWINGS OF CELESTIAL PHENOMENA.—Parts xiii. and xiv. of the current volume of *Das Weltall* contain an interesting article by Dr. W. Lehmann, of Berlin, in which the ancient Mexican accounts of solar eclipses, comets, &c., are discussed. The article is freely illustrated by drawings of eclipses, comets, the moon, planets, &c., taken from the old accounts, and these drawings are most interesting as depicting the old Mexican ideas of these phenomena. For instance, the first is a contemporary drawing of the total solar eclipse of 1531 A.D., and shows plainly immense prominences and coronal wings.

MOUNT WILSON OBSERVATORY.—In No. 2, vol. xxi., of the *Astrophysical Journal*, Prof. Hale gives an account of the conditions of solar research at Mount Wilson, California, where he has recently established the Solar Observatory of the Carnegie Institution of Washington. In the first of the two articles he enumerates the requirements of the site of such an observatory, and then discusses in detail the meteorological conditions, the seeing, the transparency of the atmosphere, and the instruments available at Mount Wilson.

In the second article the author describes the foundation, the equipment, and the programme of the observatory, and illustrates his description with photographs and diagrams of the site and of the various instruments and houses already erected or in course of erection.

ANOMALOUS DISPERSION AND "FLOCCULI."—In No. 3, vol. xxi., of the *Astrophysical Journal*, Prof. Julius advances the theory of anomalous dispersion to explain the varying appearances of the flocculi on spectroheliograph photographs. The "dark flocculi" of Prof. Hale are explained by the incurvation of the direct rays producing an excess of light in the bright flocculi, and therefore a deficit elsewhere, hence the dark regions naturally ensue.

The differences between the H_2 (calcium) and $H\beta$ (hydrogen) pictures obtained by Prof. Hale are explained by the supposition that the $H\beta$ rays are less strongly incurvated, and therefore rays of more varied refractive indices pass through the secondary slit, thereby producing a less dark and less defined image. On this assumption Prof. Julius states that the hydrogen photographs would show the fine details seen on the K_1 photographs if the dispersion employed were greater, or if the secondary slit were used narrower. Without requiring any other hypothesis, Prof. Julius explains by this theory all the anomalies seen on the spectroheliograms.

In the same journal, the same author also discusses the "dispersion bands" seen in the spectra of δ Orionis and Nova Persei, and, *inter alia*, arrives at the conclusion that the former star is *not* a spectroscopic binary.

ASTRONOMICAL SOCIETY OF AMERICA.—Abstracts of sixteen of the numerous papers read at the sixth meeting of the Astronomical and Astrophysical Society of America, held at Philadelphia last December, are given in No. 533 of *Science* by Mr. Frank B. Littel. The various titles are too numerous to mention here, but amongst them we may notice "The Constant of Aberration," by Prof. C. L. Doolittle, in which the author obtains the value $20''.540 \pm 0.0055$ from a series of zenith telescope observations made between December, 1889, and December, 1903; "The Reflex Zenith Tube," by the same author; "Variation of the Bright Hydrogen Lines in Stellar Spectra," by Miss Annie J. Cannon; "Planetary Spectrograms" and "The Canals of Mars," by Mr. Lowell; "The Coordination of Visual and Photographic Magnitudes," by Mr. J. A. Parkhurst; and "Recent Researches of the Henry Draper Memorial," by Prof. E. C. Pickering.

COLOUR IN WASPS OF THE GENUS POLISTES.

IN the paper referred to below[1] the author deals very fully with the various colour variations observable in the species of the genus under notice, and a very interesting account is given of the variability in colour-pattern, and of its gradual development in the nymphal and imaginal stages, illustrated by coloured plates i. and ii. A chemical analysis of the nature of the pigments is also given, and illustrations of the layers in which the pigments are located. Coloured plates iii. and iv. give figures of several of the different species of the genus—besides these plates there are excellent maps, showing the distribution of the various forms, and elaborate diagrams are provided, indicating the variations observable. The author has evidently spared no pains to render the treatment of the subject as exhaustive as possible, and as a study of colour variation this treatise seems to leave little to be desired. The problem attacked in this work, viz. "an inquiry into the nature and probable causes of specific differentiation in the genus Polistes," is one which is both difficult and perplexing.

The author commences at once by saying, "apart from differences in size, the characters used to separate the species are based almost exclusively on colour; accordingly, this in-

1 "Coloration in Polistes." By Wilhelmine M. Enteman. Pp. 88 6 plates. (Carnegie Institution of Washington, November, 1904.

vestigation resolves itself into a study of coloration in the genus." The conditions which make for variation in the different species are well indicated, as the author points out that, even where the inmates of a single nest are examined, the following points have to be considered:—First, that two or three females may work together for the good of one community, and may be very differently coloured; secondly, that each may be fertilised by several males, which again may be differently coloured; thirdly, that intruders from other nests may be present as they "are not always so certainly driven away from strange nests as has been affirmed for other social Hymenoptera."

In these circumstances, the attempt to distinguish the species by colour characters seems to be almost hopeless—a point, however, which seems to the present writer to have been overlooked is the possibility of the presence of unobserved plastic characters which might serve as better and more satisfactory guides to classification. That such characters exist among the palæarctic species has been demonstrated by F. F. Kohl in *Ann. K.K. Naturh. Hofmuseum*, Wien, xiii., heft i., pp. 87–90, taf. iii., who shows that five forms of the males can be easily separated by well-defined characters in the form of the clypeus and genæ, the grooves of the face, and the shapes of the subapical joints of the antennæ, and although their respective females and workers have not been satisfactorily identified, it is not improbable that careful investigation may yet disclose characters to associate the sexes of the different species together; as also it is quite probable that all the species would vary in colour in more or less parallel directions—any investigation into the distribution of the species, unless conducted with special reference to these characters of the males, would be very liable to lead to wrong conclusions. One conclusion especially to which one would like to apply the male character test is summed up in the following words:—"It is hardly probable that we have in *P. variatus* a primitive species which has differentiated in two directions, but, as we shall see from the study of the geographical distribution of the species, aurifer and pallipes are two originally distinct species which, from the course of their migration northwards, have come together in the Mississippi valley, and by their commingling produced a species having, in some measure, the characters of both." These remarks are made with no wish to depreciate, even if it were possible, this very careful attempt to investigate a most difficult problem, but merely to point out that there are characters in our Palæarctic species of Polistes which might be well looked for in those of the other hemisphere.

THE CLEAVAGE OF SLATES.

THE memoir described below[1] contains an account of experiments undertaken to test the author's theory, propounded some years ago, of the cause of the cleavage property in slates. Dr. Becker's theory, substantially the same as that put forward earlier by the Rev. O. Fisher, is that cleavage-planes are planes of maximum tangential strain, or in other words shear-planes. This is opposed to the theory of Sharpe (or, as we might say, of Sharpe and Sorby), which makes the cleavage-planes perpendicular to the maximum compression. The author has misunderstood Dr. Sorby's position, having apparently overlooked the earlier papers of that writer. The question whether heterogeneity in the rock is necessary for the production of cleavage seems to be beside the mark, since all rocks (other than glasses) are heterogeneous in this sense. Both Tyndall's wax and Dr. Becker's ceresin, being crystalline bodies, are heterogeneous, and their behaviour must depend on the orientation of the minute component crystals.

The experiments described were carried out with ceresin, a substance of the paraffin series, and some also with clay. These were submitted in one series of tests to simple compression, and in another series to shearing by means of a machine devised for the purpose. In the small masses dealt with the strains developed vary greatly from point to point, and the resulting structure is of a complex kind. We must confess that we are not convinced that the effects observed are such as to be rightly described as cleavage—they have rather the character of fractures, depending on the application of the forces which produce them, as well as on the intimate structure of the material.

It is unfortunate that no attempt is made to collate the results of the experiments with actual examples of cleaved rocks. As the author remarks, the position of the strain-ellipsoid affords a crucial test. On the Sharpe-Sorby theory the principal diametral plane of the ellipsoid must coincide with the cleavage-plane; on Dr. Becker's hypothesis it should be inclined at some angle of less than 45°. Now there are many slates in which the strain-ellipsoid is actually presented in deformed spherical concretions or colour-spots. The "birdseye" slate of Westmorland and the green-spotted purple slates of Llanberis are examples familiar to every English geologist. In every case the orientation of the ellipsoid is that which agrees with the received theory. Moreover, the spots are elliptic in the cleavage-plane itself, being elongated, as Dr. Sorby pointed out fifty years ago, in the line of cleavage-dip. If the cleavage-plane were a plane of shearing, it would correspond with a circular section of the ellipsoid.

We might object further that, since there are two directions of circular section, or of shearing, there should, on Dr. Becker's hypothesis, be always two directions of cleavage, perpendicular to one another with incipient cleavage and making an acute angle in well cleaved slates. Our author endeavours to meet this difficulty in discussing his shearing experiments. One direction of shearing is parallel to a fixed face of the block undergoing deformation, while the other is continually changing, "so that any one set of particles undergoes maximum tangential strain along these planes only for an infinitesimal time." Even assuming such conditions to be realised in nature, which cannot be the general case, we should still suppose that the cleavage-property (as distinguished from fractures set up in the process of deformation) will depend on the actual structure of the rock, not on the manner in which that structure has been arrived at.

It will be apparent from the foregoing criticism that, while recognising the intrinsic value of these experiments and the clear manner in which the author's views are set forth, we do not find in them anything which assails successfully the generally accepted interpretation of the cleavage structure.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—By direction of the Board of Geographical Studies, part ii. of the examination for the diploma in geography will be held on June 21 and two following days. No person is qualified for admission to part ii. who has not previously passed part i. (or the special examination in geography for the ordinary B.A. degree). The names of intending candidates, together with the subjects they propose to take up, should be notified to the registrary not later than May 24. The fee for admission to the examination is, for members of the university, 3*l.*; for persons not members of the university, 5*l.* The fee must be paid to the registrary not later than June 15. The subjects are regional geography, surveying and mapping, geomorphology, oceanography and climatology, the history of geography and anthropogeography. Copies of the schedules defining the range of examination may be obtained by application at the registry.

The council of the Senate has recommended that the University of Queen's College, Kingston, Ontario, be adopted as an institution affiliated to Cambridge University.

It is understood that the syndicate for considering the studies and examinations of the university, the report of which in favour of the abolition of compulsory Greek in the previous examination was thrown out last term, will continue to meet. It is proposed to add to the syndicate Mr. E. S. Roberts, master of Gonville and Caius College, Dr. Adam, one of the tutors of Emmanuel College; Mr. S. H. Butcher, late professor of Greek at Edinburgh University; and Mr. G. H. Hardy, of Trinity College. These gentlemen were on the "non-placet" side at the

last vote, but it is understood that the majority of them are in favour of some alteration in the present state of things.

A VERBATIM report of the proceedings of the Welsh national conference on the training of teachers and pupil teachers, held at Shrewsbury last November, has just been published. An account of the conference appeared in NATURE of November 17 (p. 66).

THE council of the City and Guilds of London Institute has conferred the fellowship of the institute on Mr. H. Cecil Booth in recognition of the engineering work done by him since he gained his diploma of Associate of the City and Guilds Institute in 1892.

ON Wednesday, June 7, Viscount Goschen, as Chancellor of Oxford University, will lay the foundation-stone of the new buildings of Reading University College, to be erected, at a cost of about 80,000*l.*, upon a site presented by Mr. Alfred Palmer.

AT the recent installation of Dr. Edwin A. Alderman as president of the University of Virginia, it was announced, says *Science*, that in addition to the conditional gift of 100,000*l.* from Mr. Carnegie, Mr. Rockefeller had given 20,000*l.*, Mr. Jefferson Coolidge 10,000*l.*, and alumni and friends 10,000*l.* towards the endowment fund.

MR. CARNEGIE has added another handsome donation to his many princely gifts to higher education. This time he has given 2,000,000*l.* to provide annuities for college professors prevented by old age or other physical disability from continuing to earn salaries. The gift is to be for the benefit of the United States, Canada, and Newfoundland, and applies to all universities, colleges, and technical schools without regard to race, colour, or creed, but excluding State or colonial institutes, and excluding also purely sectarian institutions. The fund is to be vested in trustees, among them Presidents Hadley, of Yale University; Eliot, of Harvard University; Harper, of the University of Chicago; Butler, of Columbia University; Schurman, of Cornell University; and Wilson, of Princeton University, all of whom have accepted. Mr. Carnegie hopes that by this endowment the best men available will be attracted to professorial work, since in view of the retiring pension, which will now be secured, present day salaries will not appear very inadequate in comparison with those of other professional men.

ON his way to Simla for the summer months, Lord Curzon visited Pusa and laid the foundation-stone of the agricultural college there. The Pusa estate comprises some 1280 acres of soil on which almost any crop may be grown. The Government proposes to concentrate there all the agricultural skill, scientific, practical, and educational, to be procured. The buildings will cost 16½ lakhs of rupees, of which amount the laboratory and its fittings will absorb 7½ lakhs. Pusa will provide for agricultural students research in the laboratory, experiment in the field, and instruction in the class-room. After laying the stone Lord Curzon, we learn from the *Times*, referred to the circumstances in which he received from Mr. Henry Phipps, the American millionaire, the munificent bequest which was the origin of the institute. The college, Lord Curzon continued, will form a centre of the application of science to Indian agriculture, and it is hoped that each province of India will in time possess its own staff, its own institute for research and experiment, in fact, a properly organised agricultural department. The Government has no desire to monopolise the field, and will lend every possible advice to great land holders conducting their own experiments, improving their own seed and the breed of their own cattle. Earlier in the day Lord Curzon, replying to an address of welcome from the Behar planters, said that the problem confronting the indigo growers since the synthetic indigo of Germany was perfected some eight years ago is so to combine scientific methods with cheapening of the cost of production as to enable them to produce a natural colour at a price permitting of competition with the artificial product.

WE have received from the Agent-General for New South Wales a copy of a "Statistical Account of Australia and New Zealand, 1903–4," by Mr. T. A. Coghlan. An important section of the volume deals with education, and a prominent place is given in this summary to university and technical education. It appears that the Government endowments to the universities of Sydney, Melbourne, Adelaide, and Tasmania in 1903 were respectively 15,533*l.*, 13,500*l.*, 6611*l.*, and 4000*l.* In addition to the annual endowment, the Adelaide University has received a perpetual endowment of 50,000 acres of land from the Government of South Australia. The University of New Zealand—which is an examining, and not a teaching, body—has a statutory grant of 3000*l.* a year from Government, and of the affiliated colleges Auckland University College is in receipt of a statutory grant of 4000*l.* a year. The University of Otago derives a sum of about 5500*l.* annually from rents of reserves. The Australasian universities are empowered to grant the same degrees as the British universities, with the exception of degrees in theology. Women are admitted to all the universities. As regards technical education, the State expenditure upon it in five of the Commonwealth provinces and New Zealand is as follows:—New South Wales, 26,500*l.*; Victoria, 16,400*l.*; Queensland, 7200*l.*; Western Australia, 5710*l.*; Tasmania, 2500*l.*; and New Zealand, 21,000*l.* In addition to ordinary technical classes throughout New Zealand, there are schools of mines in the chief mining districts, and the Government makes an annual grant of 500*l.* towards the endowment of the chair of mining and metallurgy at the Otago University. Facts such as these show that administrators in Australia and New Zealand are alive to the part which higher education should take in the life of the State, and are willing to supply funds from the public treasury to assist the work of their colleges and universities.

A LETTER from Prof. W. Ridgeway in the *Times* of April 27 contains a number of wise suggestions for the improvement of the education given to boys in secondary schools. Referring to the recent vote on the Greek question, he says, careful inquiries give reason to believe that many voted to make Greek optional simply because they believe that the system of education at present in vogue in public schools is bad, that too much time is given up to Latin and Greek, that, as a rule, science is not taught at all, that the universities are in a large measure responsible for the existing state of things, and that something must be done to improve matters; and accordingly, as somebody must be thrown overboard, Greek was the proper Jonah. Prof. Ridgeway goes on to argue that the mere abolition of compulsory Greek would not have effected any improvement in the method of teaching the older subjects in the schools or have done anything to make the teaching of science general. Moreover, he rightly remarks, there can be no reform worthy of the name which does not ensure that boys whose tastes are literary should learn the methods of science, whilst boys whose bent is to science should get a literary training to give them the power of expressing their ideas with lucidity and to imbue them with a taste for culture. The faulty teaching of the schools, he continues, is due in the main to the specialisation which is required by the open scholarship system, and to the sacrifice of the average boys to those who show greater promise and are likely to win scholarships. The universities are largely responsible for this state of things, for they deliberately encourage premature specialisation in boys of promise by their system of open scholarships, and permit the interests of the average boys to be sacrificed by allowing boys to matriculate before they have passed any examination to show that they have acquired a sufficient modicum of liberal education to serve as a basis for a university training.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 16.—"A Determination of the Amounts of Neon and Helium in Atmospheric Air." By Sir William **Ramsay**, K.C.B., F.R.S.

The author had already attempted to estimate the amounts of krypton and xenon in air by the evaporation of relatively large quantities of liquid air. No doubt much krypton and some xenon evaporated, hence the figures given were necessarily minimum estimates. Dr. Travers

and the author made a rough guess at the proportions of neon and helium in air; the amount of each gas obtained was known, but the quantity from which they were derived could only be guessed at. The figures were:—of helium one or two parts per million, and of neon one or two parts per 100,000.

The ingenious method devised by Sir James Dewar of cooling a dense form of charcoal with liquid air, and using it as an absorbent for gases, made it easy to obtain a nearly correct estimate of the amounts of the more volatile constituents. After oxygen, nitrogen, and argon had been absorbed from about 16,800 c.c. of air by exposure to 100 grams of charcoal cooled with liquid air, the neon and helium were removed with the pump. They were freed from traces of heavier gases by a similar method, and a partial, but fairly complete, separation of the two was effected in the same way. The total quantities were measured by a form of burette, in which the level of the mercury was set to a point, and the differences of pressure read.

The results are:—

	In air 1 vol. in	In crude argon 1 vol. in	Percentage By weight	Percentage By volume
Neon ...	80,790 ...	757 ...	0·000086 ...	0·0000123
Helium..	245,300 ...	2300 ...	0·00000056 ...	0·0000040
Together	61,000 ...	571 ...	— ...	—

It was not possible to detect the free hydrogen in this quantity of air; after the crude mixture of neon and helium had been mixed with a trace of oxygen and sparked for a few minutes, no contraction was observed; the volume of the gases was the same before and after sparking.

April 6.—"On Reciprocal Innervation of Antagonistic Muscles.—Seventh Note." By Prof. C. S. **Sherrington,** F.R.S.

If the crossed extension reflex of the limb be examined before and after a prolonged flexion reflex an alteration is evident in it. When a carefully adjusted electrical stimulus is at regular intervals applied to the afferent path of one limb and the resultant extensor reflex of the crossed limb is noted, it is found that if in one of the intervals a flexion reflex of the latter limb is induced and maintained for twenty seconds or more, the extensor reflex becomes altered in consequence. For a period immediately following the flexion reflex the extension reflex is increased. The intensity of the reflex is heightened, its duration is prolonged, and its latent time is reduced. If the testing stimulus be subliminal the threshold value of the stimulus required by the reflex is found to be lowered. In short, the activity of the flexion arcs directly or indirectly induces in the extension arcs a super-excitability as tested by crossed extension just as when tested by the extensor thrust.

But although this after-effect of the activity of the flexion arcs upon the antagonistic arcs, both direct and crossed, is one of increase of activity, the primary effect is, as shown previously, one of depression. In these instances there supervenes on the spinal inhibition a rebound effect of augmentation.[1]

The "spinal induction" is obviously qualified to play a part in linking reflexes together in a coordinate sequence of successive combination. If a reflex arc A during its own activity not only temporarily checks the discharge-action of an opposed reflex arc B, but also as a subsequent result induces in arc B a phase of greater excitability and capacity for discharge, it predisposes the spinal organ for a second reflex opposite in character to its own in immediate succession to itself.

Much of the reflex action of the limb that can be studied in the "spinal" dog bears the character of adaptation to locomotion. "Spinal induction" obviously tends to connect this "extensor thrust" as an after-effect with precurrent flexion of the limb. In the stepping forward of the limb the flexion that raises the foot and carries it forward clear of the ground, though temporarily checking the reflex discharge of the antagonistic arcs of extension, is, as it continues, so to say, sensitising them to respond later in their turn by the supporting and propulsive extension of the limb necessary to progression. In reflex sequences an antecedent reflex would thus not only be the means of bringing about an ensuing stimulus for the next reflex,[1] but in such instances as the above will predispose the arc of the next reflex to react to the stimulus that will arrive.

1 Sherrington, Schäfer's "Text-book of Physiology," vol. ii., p. 841, 1900.

"Further Experiments and Histological Investigations on Intumescences, with some Observations on Nuclear Division in Pathological Tissues." By Miss Elizabeth **Dale.** Communicated by Prof. H. Marshall Ward, F.R.S.

(1) This paper is the third of a series on intumescences, and deals chiefly with two plants, *Solanum tuberosum* and *Populus tremula.* On the potato plant intumescences were obtained experimentally in about twenty-four hours, either on the uninjured plants or on small fragments of leaves. The effect of nutritive solutions on the formation of intumescences was investigated.

(2) Additional anatomical observations were made, and a classification of various types of intumescences has been drawn up. The cell contents were examined and compared.

(3) The occurrence of acids and salts was investigated.

(4) The experiments show that the internal causes of intumescences are *extremely local,* and quite independent of root pressure. The osmotically active substance is probably *oxalic acid.*

The present experiments show the importance of *irritability* and *active powers of assimilation,* as well as of *moist air, heat, light,* and, generally, oxygen.

(5) Finally, the nuclear phenomena were investigated and compared, and were found to be in every respect identical in various intumescences and in wound-callus. Pathological tissues in certain plants and animals are also compared, and a strong resemblance is seen to exist between certain *rapidly* formed outgrowths in plants and animals, caused not by any parasitic organism, but simply by the influence of some stimulus, probably always external, acting upon a plant or animal in such a condition of irritability that it is able to respond. A similar resemblance occurs between regenerative wound tissues in certain plants and animals, the formation of which is in all cases accompanied exclusively by the more rapid form of nuclear division known as amitotic or direct.

Zoological Society, April 18.—Mr. H. Druce, vice-president, in the chair.—The horn-core (with sheath attached) of an Urus (*Bos primigenius*): J. G. **Millais.** The specimen was believed to be the only British example of the actual horn of the Urus in existence. The curious corrugations on the surface of the lower end were similar to those found on the American and European bison, and incidentally supported the view that the white cattle of Chillingham, Chartley, and Cadzow were not descended from this animal.—Photograph of the horns of a Roberts's gazelle (*Gazella grantii robertsi*) obtained by Mr. C. L. Chevalier: O. **Thomas.**—The discovery of the skeleton of *Diplodocus carnegii,* Hatcher: Dr. W. J. **Holland.** Dr. Holland discussed the osteology of Diplodocus, briefly pointing out some of the more interesting structural features of the skeleton, and in this connection animadverted upon certain so-called "restorations" made public in popular magazines. Dr. Holland concluded his account by exhibiting in rapid succession pictures of a few of the more remarkable skeletons which had been recovered by the palæontological staff of the Carnegie Museum from various localities in the region of the Rocky Mountains.—A unique specimen of *Cetiosaurus leedsi,* a sauropodous dinosaur from the Oxford Clay of Peterborough: Dr. Smith **Woodward.** The author described the fore and hind limbs and the tail, and confirmed the observation of the late Prof. O. C. Marsh, that Cetiosaurus was one of the more generalised Sauropoda.—On a young female Nigerian giraffe: Dr. P. C. **Mitchell.** On the evidence afforded by a young female giraffe, obtained by Captain Phillips in the district of Gummel, about 300 miles due west of Lake Chad, and now deposited in the Society's Gardens, the author was inclined to believe in the distinctness of the

1 Loeb's "Ketten-reflexe," discussed in his "Vergleichende Gehirnphysiologie u. Vergleichende Psychologie," Leipzig, 1899, p. 96, and *seq.*; compare also Exner, "Entwurf einer physiologischen Erklärung psychischer Erscheinungen," Vienna, 1894, p. 102, and *seq.*, under "Successive Bewegungscombinationen."

Nigerian giraffe (*Giraffa camelopardalis peralta* of Thomas), which, however, was closely allied to the Nubian form (*G. c. typica*).—The ento-parasites obtained from the Zoological Gardens, London, and elsewhere: A. E. **Shipley.** Thirteen species were enumerated, one of which was described as new.—The muscular and visceral anatomy of a leathery turtle (*Dermatochelys coriacea*): R. H. **Burne.** The animal was a young female about 4 feet long, and was thus considerably larger than the few examples of this rare chelonian that had previously been dissected. It came from Japan. The muscles of the neck, trunk, and limbs were described in detail, and notes were made of numerous hitherto unrecorded or imperfectly described features of the alimentary and other internal organs.—A third collection of mammals made by Mr. C. H. B. Grant for Mr. C. D. Rudd's exploration of South Africa, and presented to the National Museum: O. **Thomas** and H. **Schwann.** The present series was obtained in Zululand, and consisted of 222 specimens, belonging to 49 species, of which several were described as new, besides a number of local subspecies.—Description of a new species of newt from Yunnan: G. A. **Boulenger.**—Hybrid hares between *Lepus timidus*, Linn., and *L. europaeus*, Pall., in southern Sweden: Dr. E. **Lönnberg.** The hybrids had become comparatively common in this part of Sweden owing to the introduction of the latter species for hunting purposes.—Description of the giant eland of the Bahr-el-Ghazal: A. L. **Butler.** Mr. Butler was of opinion that this eland was more nearly allied to the West African form than to that of South Africa, and proposed to distinguish it as *Taurotragus derbianus gigas.* It differed from the typical *T. derbianus* in its much lighter body-colour (a pale *café-au-lait* fawn instead of a rich ruddy brown), in the greyish white of the black-maned dewlap, and in carrying grander horns.

Chemical Society, April 19.—Prof. R. Meldola, F.R.S., president, in the chair.—Complex nitrites of bismuth: W. C. **Ball.** A series of double salts of bismuth nitrite with alkali and ammonium nitrites and nitrates were described. These salts, though unstable, appear to be perfectly definite substances.—Experiments on the synthesis of the terpenes, part ii., synthesis of Δ^3-*p*-menthenol (8), $\Delta^{3:8(9)}$-*p*-menthadiene, *p*-menthanol (8), $\Delta^{8(9)}$-*p*-menthene, and *p*-menthane: W. H. **Perkin,** jun., and S. S. **Pickles.**—Part iii., synthesis of aliphatic compounds similar in constitution to terpineol and dipentene: W. H. **Perkin,** jun., and S. S. **Pickles.**—Part iv., synthesis of Δ^3-normenthenol (8), $\Delta^{3:8(9)}$-normenthadiene, normenthanol (8), and $\Delta^{8(9)}$-normenthene: K. **Matsubara** and W. H. **Perkin,** jun. These three papers described the preparation of terpenes and related substances. The results showed that the lemon-like odour of certain terpenes is associated with the simultaneous occurrence of two ethylenic linkages, one in the ring and the other in the side chain, and that by the disappearance of the ethylenic linkage in the ring terpenes having a peppermint odour are produced. The interesting fact was also observed that when the two ethylenic linkages occupy the so-called Tiemann position with regard to each other only one of them becomes saturated by the addition of halogens, and that consequently the property of forming a tetrabromide is not distinctive of a particular class of terpenes possessing only one double bond, as has frequently been supposed.—*C*-Phenyl-*s*-triazole: G. **Young.** This compound and certain of its derivatives were described.—The resolution of *inactive* glyceric acid by fermentation and by brucine: P. F. **Frankland** and E. **Done.** In view of Neuberg and Silbermann's observations (*Ber.*, 1904, xxxvii., 339), the authors have re-examined the barium salts of *fermentation* glyceric acid and of the synthetic acid deracemised by means of brucine, and have confirmed the results obtained by Frankland and Frew and Frankland and Appleyard, which are at variance with those recorded by the German workers.—Estimation of potassium permanganate in presence of potassium persulphate: J. A. N. **Friend.** Small quantities of potassium permanganate may be estimated iodometrically in presence of potassium persulphate provided that the solution is dilute, only faintly acid, and that the iodide is added only in slight excess of the amount required to reduce the permanganate.

Royal Microscopical Society, April 19.—Dr. Dukinfield H. Scott, F.R.S., president, in the chair.—A slide of *Bacillus typhosus* and the method adopted in staining and mounting, also photomicrographs of the slide ×2500 and 5000 diameters with flagella well displayed: W. J. **Dibdin.**—On the application of the undulatory theory to optical problems: A. E. **Conrady.**

DUBLIN.

Royal Irish Academy, April 10.—Mr. F. Elrington Ball, vice-president, in the chair.—On the growth of crystals in the contact-zone of granite and amphibolite: Prof. Grenville A. J. **Cole.** Attention is directed to the growth of crystals in amphibolites when these come under the stimulus of an invading mass of granite. Garnet and hornblende may thus appear upon a larger scale than that adopted by them in the original amphibolite. Hornblende especially grows in large prismatic forms in the composite rocks produced along such junction-surfaces, and serves as evidence in these cases that contact-alteration has taken place rather than dynamic metamorphism. Under dynamic influences, the secondary hornblende is of the granular type common in epidiorites. The instances quoted are from both sides of the Gweebarra estuary in Co. Donegal.

PARIS.

Academy of Sciences, April 25.—M. Poincaré in the chair.—Two observations relating to the undergrowth in woods: P. **Fliche.** Certain forms of plants requiring plenty of light for their proper development appear to die out when the undergrowth reaches a certain height. After clearing, however, these plants again re-appear at the same spots, and as an example of the great persistence of such plants the author instances groups of *E. lathyris,* probably planted by the Romans, which are found near Gallo-Roman remains.—On a new clutch: le **Duc de Guiche** and Henri **Gilardoni.**—On the light emitted by crystals of arsenious anhydride: D. **Gernez.** The author has made a careful study of the luminous phenomena produced during the crystallisation of arsenic trioxide, and finds that, contrary to the statements of Rose, the light is not produced at the moment each minute crystal is deposited on the sides of the flask, nor during its growth, but that the least contact between a hard body and a recently formed crystal, or between two crystals, causes a brilliant evolution of light. It is a case of the development of light by the fracture of crystals, many examples of which are known in the field of organic chemistry. This property of arsenic trioxide crystals is not a fugitive one, but is exhibited after a long interval of time.—On the application of the methods of interferential spectroscopy to the solar spectrum: Ch. **Fabry.** A description of a modification of an arrangement given in an earlier paper. It possesses the advantage of allowing a larger number of lines to be studied, and may be of use in determining very small displacements of lines.—On the variations of lustre given by a Crookes's tube: S. **Turchini.** The brightness of the fluorescent screen, when acted upon by a given Crookes's tube, was measured photometrically, each of the constants of the circuit being varied in turn. The luminosity of the screen increased with the equivalent spark up to a spark length of 10 cm. to 12 cm., after which it remained constant. Measurements were also made of the effect of the frequency of the contact breaker, of coils differing in size, and of variations in the self-induction of the coil.—The application of the microscope to the examination of india-rubber: Pierre **Breuil.** It was found that the progress of the vulcanisation of rubber could be followed under the microscope, the absorption of the sulphur being accompanied by changes in the crystalline structure.—The floral diagram of the Cruciferæ: M. **Gerber.** The floral formula of the Cruciferæ is given as

$$S(2_l+2_m).P(4_d).E(2_l+4_d).C(2_{ls}+2_{mf}).$$

—The experimental production of the ascospore apparatus of *Morchella esculenta*: Marin **Molliard.** From the experiments described the best conditions are worked out for the cultivation of this mushroom.—Chlorophyll assimilation in young shoots of plants; applications to the vine: Ed. **Griffon.** Boussingault, in 1807, studied the question

as to whether young shoots, almost colourless, possessed the power of decomposing carbonic acid, his experiments leading to a positive result. The method used was indirect, the assimilation being proved by the evolution of oxygen. The author has taken up this question again, using the method of gaseous exchanges in a confined atmosphere containing from 5 per cent. to 10 per cent. of carbon dioxide. In the cases studied the assimilation was extremely small, and was easily masked by the respiration.

CALCUTTA.

Asiatic Society of Bengal, April 5.—The colouring principle of the flowers of *Nyctanthas arbor tristis*: E. G. **Hill.** The author describes the uses of the flowers of the "Narsinghar" plant in dyeing, and gives an account of the separation and properties of the crystalline yellow colouring matter. A sweet principle, recognised as mannitol, and wax were also extracted from the flowers.—On some forms of the Krīs hilt, with special reference to the Krīs Tádjōng of the Siamese Malay States: N. **Annandale.** The Krīs is the most characteristic weapon of the Malays, but its origin is probably not very ancient. The hilt takes various forms, all of which, however, have much in common, and can be reduced to one general type. Examination of a series of specimens shows that this type was originally Hindu.—On the occurrence of the fresh-water worm Chætogaster in India, with a diagnosis of a species from Calcutta and notes on its bionomics: N. **Annandale.** The genus Chætogaster does not appear to have been recorded hitherto from India. A species (*Chaetogaster bengalensis*, sp. nov.) common in the Calcutta tanks lives in close association with water-snails, but is not parasitic upon them, feeding on small Crustacea. It progresses by the aid of an anterior and a posterior sucker, and uses its setæ in insinuating itself between the snail and its shell.

DIARY OF SOCIETIES.

THURSDAY, MAY 4.

ROYAL INSTITUTION, at 5.—Flame: Sir James Dewar, F.R.S.
CHEMICAL SOCIETY, at 8.—The Synthesis of Substances Allied to Adrenaline: H. D. Dakin.—Methylation of *p*-Aminobenzoic Acid by Means of Methyl Sulphate: J. Johnston.—Some Notes on Sodium Alum: J. N. Wadmore.—Camphoryl-ψ-Semicarbazide: M. O. Forster and H. E. Fierz.
RÖNTGEN SOCIETY, at 5, (1) to Medical Members only. Forty-two Cases of Ureteral Calculus Diagnosis by X-Rays proved by Operation on the Passage of the Calculi; (2) at 8.15 p.m., to the General Meeting, Measurement and Technique in Therapeutic Dosage: Dr. C. Lester Leonard, Philadelphia.
LINNEAN SOCIETY, at 8.—Œcology: its Present Position and Probable Development: A. G. Tansley.—The Flora of Gough Island: R. N. R. Brown.
CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 7.30.—Annual General Meeting.—At 8.—Card-Indexing and Filing: J. C. Osborne.

FLOW OF UNDERGROUND AND RIVER WATERS.

Essais d'Hydraulique souterraine et fluviale. By Edmond Maillet, Ingénieur des Ponts et Chaussées. Pp. vi+218. (Paris: Librairie scientifique, A. Hermann, 1905.) Price 11 francs.

THIS treatise, which was presented in the first instance to the Academy of Sciences of Paris in 1903, is divided into two parts, the first theoretical and the second practical, to which a paper has been appended, mainly of a practical nature, on the curves of the discharge of springs and the abatement of river floods. The book is addressed to mathematicians, physicists, geologists, geographers, meteorologists, engineers, and all who are interested in the motion and the distribution of rainfall, both on the surface of the land and underground; and its object is to investigate theoretically and practically the variations in the discharge of springs, and the low-water flow of rivers, in order to be able to foretell the amount of this minimum flow, precisely as the height of the floods of rivers is predicted, as already effected in certain cases by French hydraulicians, such as Dupuit, Belgrand, Lemoine, de Preaudeau and others, and also recently by the author with respect to two of the sources of the River Vanne.

M. Maillet believes that he is the first to have indicated a method by which exact quantitative discharges can be systematically predicted, such as a graphic curve, based upon Dausse's law concerning the permeable strata of the Seine basin, enabled him to determine the yearly minima discharges of two sources of the Vanne several months beforehand. Later on, by means of the hypothesis of a particular form of the free water-surface, he succeeded in obtaining a law which proved to be in accordance with experience, as indicated in the first half of the theoretical portion of the book. In the second half of this portion, the stability, or the nature of the motion of underground waters, under different conditions, is investigated, allowing for the increase in volume produced by rain; and assuming a simple form for the impermeable bed over which the water flows, it is shown that where the line of the bed is convex upwards the maximum height of the flood will be rapidly attained, and where concave, the flood will rise slowly, and that the influence of a part of the stream on the maximum will be greater in proportion to the fall of the bed. The connection, also, between the low-water levels, or minima discharges, at any point of a watercourse or spring and the rainfall, is considered in as general a form as possible; and it is proved that, in practice, the lowest discharge may often be regarded as a function of the combined rainfall of the preceding hot and cold seasons, and experiences very slight variations from year to year, especially in large river basins, unless the warm season is very rainy and impermeable strata intervene.

The results of the theoretical investigations comprised in the first six chapters are summed up in the three following laws:—(1) A certain number of hydrological facts, corresponding to the low stages, or minima discharges, of springs or watercourses, in many cases depend almost exclusively on the total rainfall of several preceding warm and cold seasons. It is only in the case of restricted watersheds that the rainfall of the last one or two cold seasons exercises a predominating influence, the number of preceding years on which the results depend increasing in proportion to the size of the basin. The preceding warm seasons have less influence than the following cold seasons; and they both have less influence in proportion as they date further back, though this loss of influence varies inversely with the size of the basin. The immediately preceding spring and summer rainfalls may introduce an element of disturbance if they are heavy and widespread, supposing that the permeable strata predominate in the basin; but where the basin is almost wholly permeable, the rainfall of the preceding warm seasons may often be neglected. (2) The lowest level at a given point of a watercourse in any year is approximately a function of the minimum level of the preceding year, and of the amount of rain during the preceding cold season, and some preceding months of the warm season if very wet or very dry, provided the proportion of impermeable strata in the basin is small. In the case of many watercourses, the minimum yearly level varies little from year to year; and a succession of several years, or several cold seasons, more rainy or more dry than the average, is needed to produce modifications, which, moreover, are slow and progressive with the lapse of time. (3) In the Seine basin, the low-water levels at given points of many of the watercourses draining almost wholly permeable strata, differ little from their mean secular height. These variations cannot be abrupt, except under the immediate influence of rainy summers on the impermeable strata of the basin; and in any case they would be progressive, as a result of a gradual increase in the mean rainfall for a certain number of years. Subject to these reservations, an appreciable variation in the low-water level must be due to other than meteorological causes.

The second, practical, part of the book occupies little more than a third of the space devoted to theoretical considerations, though divided into ten chapters, which are, consequently, very short for the most part. It contains some practical applications of the views and theories developed in the first part, to the prediction of various hydrological phenomena, and also some experimental verifications; and the works of Belgrand, and the observations and publications of the hydrometric service of the Seine basin, form the basis of this inquiry. After a very brief introduction, the chapters deal successively with proportion of rainfall which feeds underground waters, prediction of the drying up of the sources of the Somme from the rainfall, prediction of the discharges of Cérilly spring, a source of the Vanne, prediction of the minima discharges of the sources of the Vanne, application to the sources of the Dhuis, prediction of the low-water levels of the Marne at La Chaussée, drying up of the Laignes, remarks on springs supplying Havre, and

great floods of the Seine; and thirty-one tables are appended at the end of the volume, giving the rainfall, discharges, and water-levels at different dates in various parts of the Seine basin, and eleven sets of graphic curves indicating the decrease in the discharges of the Seine, some of its tributaries, and certain sources, at different periods. Table xxiii., giving the rainfalls of the warm seasons, and the high floods of the following cold seasons, at the Austerlitz Bridge, Paris, and at Mantes, from 1874 to 1900, shows that none of these warm seasons in which the rainfall was below the mean of 14.88 inches, was followed by floods of the Seine rising higher than 14.44 feet on the gauge at Paris, and 19.72 feet at Mantes; and the eight cold seasons in which the Seine reached or exceeded 16.40 feet at Paris, and 21.06 feet at Mantes, were all preceded by warm seasons in which the rainfall exceeded the mean. Moreover, with the exception of 1890, when the warm season came between two very dry cold seasons, all the warm seasons having a rainfall above the average have been followed by floods of the Seine, attaining at least 10.17 feet at Paris and 16.40 feet at Mantes; whereas none of the fourteen warm seasons with a rainfall below the average was succeeded by floods in the next cold season, reaching the height attained in eight of the cold seasons preceded by warm seasons in which the rainfall exceeded the average.

A NEW AMERICAN WORK ON THE CALCULUS.

Elements of the Differential and Integral Calculus. By William Anthony Granville, Ph.D., with the editorial cooperation of Percey F. Smith, Ph.D. Pp. xiv+463. (Boston and London: Ginn and Co.) Price 10s. 6d.

THIS is a book the main object of which seems to be to enable the student to acquire a knowledge of the subject with little or no assistance from a teacher; and, after a very careful study of it, we are enabled to say that the work is admirably constructed for the purpose. There is a complete absence of the stilted formality which is usually supposed to be appropriate to a mathematical treatise. In foot-notes, and sometimes in the text, the student is given scores of useful hints and warnings against errors into which he would probably fall. Thus the work possesses a very high value for the student; and it will be found no less helpful to the teacher, for it contains a very large number of examples in every part of the subject, while it abounds in excellent diagrams.

The portion on the differential calculus occupies 285 pages, and terminates with 6 pages containing nothing but figures of all the curves more or less famous which present themselves in the subject, such as the conchoid of Nicomedes, the cycloid, the catenary, the cissoid of Diocles, the probability curve, various spirals, &c.

The work is very strictly logical in its method—here and there a little too much so, perhaps.

Thus in p. 97 the proof that the angle between the radius vector and the tangent to a curve has $rd\theta/dr$ for its tangent is quite unnecessarily accurate, and has involved an error in work, which, however, is a mere slip. The theorem of mean value is very well explained and used in the deduction of Taylor's theorem for the determination of the remainder, a little geometrical figure assisting the student to understand the nature of this remainder. (Correct, however, the errors in sign in the first equation of p. 169.)

The discussion of the convergency and divergency of series is very good, and a somewhat uninteresting subject is rendered simple and attractive. An incautious statement, however, is made with regard to an alternating series, p. 241, according to which if we stop at the nth term of such a series the error made is numerically less than the value of the $(n+1)$th term. Clearly this is not in general true if the alternating series is one in which the numerical values of the terms increase for a while and then diminish. For example, the series for sin x is an alternating one of this kind. If $x=5$, the numerical values do not begin to diminish until after the third term. The property asserted, and the proof in p. 226, must be applied to cases in which we stop after the greatest numerical term has been passed.

The theory of maxima and minima is well illustrated by examples taken from various branches of physics. Even at the risk of being a little hypercritical, we must, however, point out that the time taken by a ball to roll down a plane the base of which is of length a and the inclination of which is ϕ is not $2\sqrt{a/g}$ sin 2ϕ, as it is said to be in p. 128, for the simple reason that the acceleration of the centre of the ball (if the ball is solid and homogeneous) is not g sin ϕ, but $5/7$ g sin ϕ. This fact is of importance in dynamics, and the matter should be set right.

The part of the book dealing with curves is very good, and, in particular, we would commend the systematic manner in which (pp. 267, 268) the student is taught to trace a curve from its equation.

In the portion dealing with the integral calculus an exhaustive exposition of all the devices used in integrating functions is given. The reduction formulas to be applied to the binomial integral $\int x^m(a+bx^n)^p dx$ are given in tabular form on p. 345, and the student is told very properly that he should not memorise them. Instead of memorising them, he should apply a single simple rule which was given long ago by Hymers in his "Integral Calculus." This rule enables us to obtain, without an effort of memory, the exact formula appropriate to the reduction of any given binomial integral.

Besides areas and volumes (accompanied by excellent figures), polar moments of inertia of plane areas are dealt with. The author speaks of these as moments of inertia about "a point"—an expression which leaves something to be desired, since it is always an *axis* that is involved. What we always require in this connection in dynamics is the *mean square of distance of a body from an axis,* and we should look to writers on the calculus to emphasise this notion of a mean square of distance, instead of the "square of the radius of gyration," k^2. The

student might easily learn to regard k as the *distance of mean square*, just as we speak of the *velocity of mean square* in a gas.

The book has a useful chapter on the simpler forms of differential equations, and concludes with a figure and description of the integraph for finding the area of a curve. It might well include a description of Amsler's planimeter, and show how it finds areas, positions of centres of gravity, and moments of inertia of plane figures; and, as to the proof of the theory of Amsler's planimeter, it need occupy no larger space than the area of a shilling, notwithstanding the length and complication of proofs which are usually given.

The author's attention may be directed to the following misprints:—p. 44, note, Leibnitz was Gottfried, not Gottfreid; p. 206 (A), read f'_x for f_x; p. 216, ex. 15, read v_0^2 for v_0; p. 225, line 5, read 223 for 225; p. 275, line 6, read P′ for P; p. 374, line 1, read y for dy.

GEORGE M. MINCHIN.

SERUM DIAGNOSIS.

Manual of Serum Diagnosis. By O. Rostoski. Authorised translation by Charles Bolduan. Pp. vi+96. (New York: J. Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 1 dollar.

THIS small work forms a companion volume to that by Wasserman on "Hæmolysins and Cytotoxins," which has already been noticed in these columns. Each volume forms a monograph on some part of those newer developments of bacteriology which concern immunity and kindred subjects. The aim of the series is to provide simple yet comprehensive accounts of our present knowledge suitable for those who do not make a special study of the laboratory aspects of disease rather than exhaustive treatises adapted for special students. That the information is authoritative and trustworthy is vouched for by the list of authors, which includes some of the most distinguished names in contemporary bacteriology. Each volume is the work of one who has himself made important contributions to the study of the subject.

The present volume deals with the practical use of agglutinins, bacteriolysins, and precipitins in diagnosis. More than two-fifths of the whole is devoted to an account of the Widal reaction in enteric fever. This section is extremely good, and for it alone the book is well worth reading. The author points out very clearly that the "test" is not to be regarded as more than the "first of the cardinal symptoms of typhoid." Some discredit has been cast on the value of the reaction, because clinicians have not always found that infallibility which is so often expected of the laboratory, but which can never be present in dealing with so variable a complex as living matter. Removed from the pedestal of a "test" to the common ground of a "symptom," the phenomenon seems to have a better chance of receiving the appreciation which it deserves. There is an admirable account of the mixed and "group" agglutinations in typhoid and paratyphoid infections, and due notice is taken of the use of typhoid cultures which have been killed by the addition of formalin. These react practically as well as living cultures; and, though the increased time required to obtain a result and the slight loss of delicacy render the use of living cultures still desirable in the laboratory, the safety and convenience of the dead cultures place the "test" within the personal practice of every not-too-busy practitioner. It is, however, strange to read (p. 13) that the use of an oil-immersion objective is necessary.

The author then considers briefly the agglutination phenomena found in tuberculosis, dysentery, and other diseases. Serum diagnosis of tubercle is considered to be of very doubtful value. Appropriate stress is laid on the fact that in many diseases (especially plague and cholera) agglutination, in comparison with other symptoms, is of very little use for the direct diagnosis of the disease, though of the greatest value in the identification of the isolated organism. This part of the book is, however, less satisfactory than the earlier sections. Indeed, the serum diagnosis of Malta fever is not mentioned, though the practical value of the phenomenon in the diagnosis of this variable and often very obscure disease has been demonstrated beyond question.

The book concludes with an account of the identification of blood stains by the precipitin test. Readers will find here a wise injunction to make sure that any given stain is blood before deciding whether it is of human or animal origin; the precipitin will not distinguish between the different tissues of the same species of animal in the same way as it will separate the same tissue from different species.

In the translation several useful additions have been made; the last chapter, which attempts an impossibly precise and entirely arbitrary definition of the Widal reaction, might, however, well have been omitted.

A. E. B.

HISTORY OF PHARMACY.

Geschichte der Pharmazie. By Hermann Schelenz. Pp. ix+934. (Berlin: Julius Springer, 1904.) Price 20 marks.

THE successful practice of pharmacy implies some acquaintance with plant chemistry and with that branch of economic botany known as *materia medica*. For this reason the history of pharmacy, although it appeals particularly to the pharmacist and the physician, presents also many points of interest to the chemist and the botanist. Herr Schelenz does not consider that the classes of readers here enumerated form a sufficiently wide circle for his purpose, and he states in the preface to this volume that he hopes also to interest the legislator, the antiquarian, and the philologist.

The book begins with a description of the conditions under which pharmacy was practised among the Jews. A summary of the political history of the nation is first given, and this is followed by sections dealing with Biblical and Talmudic references to the practice of pharmacy and the social condition, &c., of the practitioners of the art. The most interesting portion of this section is that describing the drugs employed by Jewish apothecaries. It is curious that so many of these are still in use at the present day;

for example, myrrh, Indian hemp, cassia (or cinnamon), coriander, colocynth, galls, almonds, galbanum, and storax are among those mentioned by the author. The Jews also appear to have made use to some extent of natural mineral waters and various medicated baths as remedial agents.

Similar accounts of the practice of pharmacy among the Phœnicians, Assyrians, Egyptians, Hindus, Persians, Greeks, Romans, and other peoples are given, and then this racial method of treatment is interrupted, and a chapter is inserted giving an account of the methods of the professors of magic, astrology, and alchemy in the Middle Ages, and showing how the practice of these secret arts gradually led to a knowledge of natural science.

Resuming his narrative after this digression, the author deals with pharmacy among the Copts and Syrians, the Arabs, and the Teutonic races, and brings it to the close of the eighteenth century with a short account of the condition of medicine and pharmacy in Italy, when the school of Salermo exercised a paramount influence on these arts. It was at this period that a definite separation of pharmacy from medicine first took place.

Each of the succeeding chapters deals with the progress made during a particular century, an outline of the additions to physical, chemical, and botanical sciences being first given, with short biographies of the more famous exponents of these sciences. The bearing of these discoveries on pharmaceutical methods is then outlined, and finally the legislation of the periods, the social and commercial conditions, and other matters in so far as they affected the practice of medicine and pharmacy are discussed.

The book is evidently the outcome of much literary and antiquarian research on the part of its author, but it is unfortunate that more care was not exercised in selecting the material to be included. There is no reason why so much space should be taken up in recounting the political and religious histories of the various peoples. Similarly, the short and necessarily inadequate biographies of eminent men of science, which are scattered broadcast through the second half of the book, might well have been omitted, since they are already better done elsewhere. By omitting these and other not strictly relevant matters, the size of the volume could have been much reduced, and at the same time it would have been unnecessary for the author to write in the compressed, unreadable style which now characterises the book. As it is, the volume can only be regarded as a useful work of reference on the history of pharmacy and allied subjects, and to this purpose its index (26,000 entries) is well adapted.

T. A. H.

OUR BOOK SHELF.

Guide to the Gallery of Birds in the British Museum. Pp. iv+228; illustrated. (London: Printed by Order of the Trustees, 1905.) Price 2*s.* 6*d.*

THIS handsome volume is a new departure in the matter of "guides," so far as the natural history branch of the museum is concerned, being larger in size, more fully illustrated, different in style, and (perhaps most important of all) higher in price than those to any of the other sections. The text is, in fact, a concise synopsis of the leading groups of birds, with special reference to the specimens exhibited in the galleries. The plan of the synopsis necessarily follows the system adopted in the museum, and it would therefore be quite out of place to criticise that system on the present occasion. A similar remark applies to the fact of the illustrations (which are admirable of their kind) being taken from the stuffed specimens in the collection instead of from living birds—the guide is to illustrate the collection, and therefore it is quite right and proper that the figures of the birds should be taken from those shown in the gallery. In addition to the general synopsis, there is a guide to the series of British nesting birds. That the general plan and execution are in the main excellent cannot be denied; whether it will suit the taste—and the purses—of the public remains, however, to be seen.

When a new edition is called for, certain emendations may with advantage be made in the text. The most serious error we have detected is the statement (p. 11) that the largest Æpyornis was probably not more than 7 feet in height, whereas there are actually limb-bones in the museum itself which are nearly of these dimensions; such an error implies a want of cooperation between the zoological and palæontological departments of the museum. Of less importance, although far more embarrassing to the public, is the discrepancy between the terminations of the "orders" of ostrich-like birds in the list on p. 8 and those in the synopsis on that and the following pages. Again, we venture to think that the public will not be likely to understand the semi-scientific jargon frequently employed in the text. The expression, for instance, on p. 106, "the remarkable Australian forms constituting this order," would have been much better had the word "birds" been used in place of "forms." Neither is the construction of the sentences in all cases so good as it might be, as witness the following (p. 64):—"The appendage opens under the tongue and is largest in the male, giving the bird a very peculiar appearance. Like its allies it is an expert diver . . ."

R. L.

A Laboratory Manual of Organic Chemistry for Beginners. By Dr. A. F. Holleman. Translated by A. Jamieson Walker, Ph.D. Pp. xiv+78. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 4*s.* net.

THE preparation and properties of a number of organic compounds are dealt with in short paragraphs in a manner reminding one of the text-books of qualitative analysis, which are now so universally condemned. But little attempt is made to indicate the quantities which should be used, and no emphasis whatever is laid on the importance of making organic preparations in a quantitative manner. We even doubt whether the beginner would attain the required result in performing many of the preparations described.

It will be a sad day for the future of organic chemistry if text-books such as Dr. Holleman's come into general use; it is indeed difficult to imagine anything more calculated to encourage scamping of laboratory work. A growing complaint of the chemical manufacturer abroad at the present time is that the university graduates from the large modern laboratories are ruined by the elaborate apparatus, ready-made reagents and other time-saving appliances placed at their disposal, so that they are no longer themselves capable of facing practical problems properly or of making the best use of the ordinary technical appliances. The physical chemical epoch from which chemical science is now slowly recover-

ing has caused it to be forgotten that for successful work in chemistry it is essential that the investigator be a highly skilled manipulator. It is too often found that the best student in the examination room is all but worthless when set to perform even the simplest piece of experimental work; good workers can only be trained by the most careful and thorough grounding in making pure chemical preparations and by being taught to appreciate the importance and necessity of even the minutest details in the process. As a glance at the modern chemical literature shows, it is precisely this attention to detail which is so conspicuous a feature in some of the best work.

We fear that the book under notice would not lead the student to attach importance either to accuracy of method or to thoroughness of detail; it seems a pity even that it should have been found worth while to translate it and so add another to the legion of text-books.

Metaphysik in der Psychiatrie. By Dr. P. Kronthal. Pp. 92. (Jena: Gustav Fischer, 1905.) Price 2.50 marks.

THIS costly little work is written to ventilate a grievance. It would appear that certain authorities on mental diseases, including Kräpelin and Binswanger, employ in their works such terms as association, apperception, power of imagination, anger, and the like. These, according to our author, are metaphysical terms, and must be carefully excluded from *Psychiatrie,* which is a purely natural science. New sciences spring up like mushrooms nowadays, and it is a misfortune that those who specialise in one, or seek to exploit it, so rarely know with precision what is being done in others, even when these are most closely akin to their own darling pursuit. We fear that this writer hardly understands that the terms which he criticises are used every day in psychology with a minimum of metaphysical reference, and that he is almost bound, before he proceeds a step, to show due cause why the terminology of *Psychiatrie* should differ seriously from that accepted by ordinary psychology. In spite of his parade of footnotes and his references to such grand conceptions as that of *Allbeseeltheit,* it may be doubted if this writer is competent to discuss so general a question. At any rate, his present work does not impress one as being well arranged, clear, or convincing.

A Text-book of Physiological Chemistry. By Charles E. Simon. Second edition. Pp. xx+500. (London: J. and A. Churchill, 1905.) Price 15*s*. net.

ALTHOUGH Dr. Simon's book has reached a second edition, it is one which has been hitherto unknown on this side of the Atlantic. Dr. Simon's name is not associated with any researches in physiological chemistry, and there is nothing strikingly new or original in his book, either as regards subject-matter or arrangement. The work has, however, many excellent features. It is clearly written, and is free from inaccuracies; the sections dealing with the proteids and their cleavage products are especially good, and fully abreast of the recent advances which have been made in this important and interesting branch of the subject.

The author is conversant with chemical technique, and his descriptions of analytical processes are specially lucid. It is evident that he is a careful student of chemico-physiological literature, and more especially with that part of it which originates in Germany. This is frequently seen in the nomenclature he adopts. Thus he speaks of casein and paracasein instead of caseinogen and casein respectively as employed in most English books. Occasionally the adherence to German terms leads to confusion; for instance, the two German words Eiweisskörper and Albumine are both translated as albumins.

The work is primarily intended for students, and therefore references to literature are omitted. A desire to keep the book within a moderate compass has no doubt induced the author to leave out a consideration of many subjects which might well have been expected to find a place in it. Thus we find no reference to the important subject of immunity and its side issues, like the precipitin test for blood. The numerous investigations now in progress on the velocity of ferment action are passed over in silence. Physical chemistry has during the last decade made great progress, and many and important are its applications to physiology. Such questions as absorption, secretion, osmosis, gaseous exchanges, and electrical conductivity have all been made clearer by the work of the physical chemist; but there is no reference to any of such investigations.

The strangest and most important omissions, however, are the absence of any account of general metabolism, animal heat, and respiration.

Turning to the title-page, one searches in vain for the words vol. i., for the omitted material would easily fill a second volume of the same size. One cannot help thinking that, interesting and instructive as the book undoubtedly is, it cannot be expected to take its place as a favourite until the deficiencies alluded to are rectified.

Astronomy for Amateurs. By Camille Flammarion. Translated by Frances A. Welby. Pp. 340. (London: T. Fisher Unwin, 1905.) Price 6*s*.

MUCH that is interesting to amateur astronomers may be found in this volume. The descriptions are often discursive, but the matter is there, and in a readable form providing the reader's leisure is not too limited.

After a general exhortation to his readers to study and contemplate the marvels of the sky, the author proceeds to a study of the constellations, the stars themselves, the sun, and then the planets. Next follows a chapter on comets, containing some interesting facts concerning the ancient ideas of these "glittering, swift-footed heralds of Immensity," and a brief account of comets in general and of a few in particular. Shooting stars are then dealt with, and in chapters viii., ix., and x. the earth, the moon, and eclipses are severally discussed. In chapter xi. the more elementary methods of determining stellar distances and masses are described, whilst the next, and last, chapter is devoted to a discussion of life universal and eternal. The book contains eighty-four illustrations—the relevance of some of which is open to question—and it will be read with both interest and profit by those whose previous acquaintance with astronomical truths has been slight.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Scientific Correspondence of the late Sir George Stokes.

ARRANGEMENTS are in progress for the publication of a selection from Sir George Stokes's scientific correspondence. The letters addressed to him, which are now in my custody, show that there must be many from him to others, of permanent scientific value, to which I have not access. I shall therefore be glad if owners of letters of *substantial scientific interest* will entrust them to me, to be treated with care and ultimately returned. J. LARMOR.

St. John's College, Cambridge, May 8.

The Transposition of Zoological Names.

I WISH to say how thoroughly I agree with Mr. Lydekker in his remarks on the unwisdom of transposing zoological names, and on the confusion caused by this objectionable practice. To the instances which he has mentioned I may add the following cases relating to two well known and familiar species of animals. Linnæus called the only European hare known to him *Lepus timidus,* and for many years that name was applied to the common brown hare of Central Europe, while the northern hare, which changes to white in winter, was known by Pallas's appropriate name, *Lepus variabilis.* This was the nomenclature used by Blasius, by Bell in his "British Quadrupeds," and in all the ordinary text-books of zoology. It was, however, pointed out some years ago, first, I believe, by Lilljeborg, that the *Lepus timidus* of Linnæus had been based mainly upon the northern or variable hare, or that at all events Linnæus had confounded the two species together. In these circumstances obviously the best plan was to call the middle-European brown hare by its next given name, *Lepus europeus,* and this course has been adopted by most writers. But the advocates of unrestricted priority are not content with this, and insist upon calling the variable hare *Lepus timidus,* the consequence being that when that name is used it is impossible to know which of two perfectly distinct animals is intended by it.

Another still more objectionable transposition of two well known names has been lately suggested. Linnæus, in the *twelfth* edition of the "Systema Naturæ," gave the name *Turdus musicus* to the song-thrush and that of *Turdus iliacus* to the redwing, and these familiar terms have been used by all writers for these well known birds respectively ever since. But about a year ago it was discovered by an ardent member of the new school of priority that in his *tenth* edition of the "Systema" Linnæus had unfortunately (by some error in his MS. or of his printer) attached the diagnosis of *Turdus musicus* to *T. iliacus,* and that of *T. iliacus* to *T. musicus.* It was admitted that Linnæus had corrected the mistake in his later edition of 1760, but even Linnæus could not be allowed to correct his own errors in the face of the inviolable law of "priority." In future, therefore, it was maintained, the song-thrush must be called *T. iliacus* and the redwing *T. musicus!* This course has been actually adopted by a subsequent writer, but we may trust that it will not meet with general approval, and that the song-thrush and redwing will remain under the old names given to them by the father of scientific nomenclature in 1760, and used by every subsequent writer until 1904. P. L. SCLATER.

Modern Algebra.

THE publication of Messrs. Grace and Young's treatise on algebra will direct attention to the importance and difficulty of the theory of the concomitants of ternary and quaternary quantics in connection with plane and solid geometry. There are one or two points on which I propose to make some remarks.

In the first place, canonical forms are sometimes deficient in generality, and this will be the case whenever the form is the analytical expression for some *special* property of an anautotomic curve. Of this defect the canonical form of a ternary cubic furnishes a striking example, for it is the analytical expression for the theorem that through each of the three real points of inflexion one real straight line can be drawn which passes through one pair of conjugate imaginary points of inflexion on an anautotomic cubic curve; and since autotomic cubics do not possess this property such curves cannot be represented by the canonical form.

In the next place, anautotomic curves are not by any means the most interesting species of curves, and to go through the process of calculating their concomitants, and then specialising them for some particular species of autotomic curves, is often very laborious. In the case of unicursal quartics, many interesting results might be obtained by calculating directly the concomitants of the quantic $(*\between\beta\gamma,\ \gamma\alpha,\ \alpha\beta)^2$, and this would give results applicable to all unicursal quartics, except those which possess the five compound singularities called the tacnode, the rhamphoid cusp, the oscnode, the tacnode cusp, and the triple point. Also, since an evectant is the tangential equation of a curve which is related in a special manner to the original one, an examination of the evectants of the above quantic would lead to interesting results concerning conics and other curves connected with trinodal quartics.

In this subject geometrical methods are a powerful assistance to pure analysis. For example, let U be a ternary cubic in (α, β, γ); eliminate γ by means of the equation $\beta=k\gamma$, and equate to zero the discriminant of the resulting cubic equation in α/β. This will give a sextic equation $\Delta(k)=0$, which determines the six tangents drawn from A to the curve. The condition that the curve $U=0$ should have a node is that the equation $\Delta(k)=0$ should have a double root; hence the discriminant of this binary sextic is the discriminant of the original ternary cubic U.

Many other examples of a similar kind could be mentioned, and we may observe that from the discriminant of a binary duodecimic, all the conditions that a quartic curve should possess *point* singularities may be obtained.

Current Theories of the Consolidation of the Earth.

IN Lord Kelvin's philosophical and justly celebrated paper on the secular cooling of the earth (Thomson and Tait's "Nat. Phil.," vol. i., part ii., Appendix D), the assumption is made that the earth was once a fiery molten mass, liquid throughout, or melted to a great depth all round. He cites Bischof's experiments showing that "melted granite, slate, and trachyte all contract by something about 20 per cent. in freezing," and continues:—

"Hence, if, according to any relations whatever among the complicated physical circumstances concerned, freezing did really commence at the surface, either all round or in any part, before the whole globe had become solid, the solidified superficial layer must have broken up and sunk to the bottom, or to the centre, before it could have attained a sufficient thickness to rest stably on the lighter liquid below. It is quite clear, indeed, that if at any time the earth were in the condition of a thin shell of, let us suppose, 50 feet or 100 feet thick of granite, enclosing a continuous melted mass of 20 per cent. less specific gravity in its upper parts, where the pressure is small, this condition cannot have lasted many minutes. The rigidity of a solid shell of superficial extent so vast in comparison with its thickness, must be as nothing, and the slightest disturbance would cause some part to bend down, crack, and allow the liquid to run over the whole solid. The crust itself would in consequence become shattered into fragments, which would all sink to the bottom, or meet in the centre and form a nucleus there if there is none to begin with."

In adhering to these views, Lord Kelvin has been followed by Prof. G. H. Darwin (*cf.* "Tides and Kindred Phenomena of the Solar System," p. 257) and other eminent mathematicians; so that the theory that the earth consolidated by the building up of a solid nucleus through the sinking of portions of the crust of greater specific gravity is no doubt generally accepted by geologists and others interested in the physics of the earth.

Recent researches on the pressures within the planets (*cf. Astronomische Nachrichten,* No. 3992) have thrown great doubt on this mode of consolidation of the globe. The line of argument by which we reach this conclusion is a double one:—

(1) It is shown that the effect of pressure in the highly heated fluid assumed to have constituted the molten earth would have been to dissolve the portions of the sinking crust before they attained any considerable depth.

(2) The increasing density of the fluid itself would have prevented sinking of the crust below one-tenth of the radius, so that a solid central nucleus could not have been built up in this way.

To see this clearly, let us suppose that the earth were a molten mass, and that a crust of rock several kilometres in area, and a considerable fraction of a kilometre in thickness, had formed, and begun to sink in the molten fluid

by its superior gravity. What would happen to it as it descended towards the earth's centre?

The densities and pressures in the outer layers of the earth, found by Laplace's law, are as follows:—

Radius	Depth below the surface km.	Density	Pressure in atmospheres
1·000	...	2·55	1·000
0·995	31·85	2·608	8,610
0·990	63·70	2·667	16,470
0·985	95·55	2·725	25,080
0·980	127·40	2·785	33,690
0·97	191·10	2·904	51,670
0·96	254·80	3·025	70,410
0·95	318·50	3·144	89,400
0·94	382·20	3·265	109,860
0·93	445·90	3·386	130,130
0·92	529·60	3·508	152,940
0·91	593·30	3·629	175,470
0·90	657·00	3·751	198,760

The above table shows that before the mass has descended 31·85 km. (1/200th of the radius) the pressure about it would have become more than 8000 atmospheres, which would force the molten fluid deep into the heated rock. The rising temperature at that depth would also rapidly dissolve the mass, and before the solid has sunk through another equal space in the viscid liquid, and thus reached a depth of 63·7 km., it seems almost certain that it would be completely dissolved.

It must be borne in mind that the solid is not much denser than the liquid; and as the liquid is highly viscous the mass would sink slowly, while the increase of temperature and pressure would conspire together in the most powerful manner to dissolve the mass and reduce it to the same temperature and density as the enclosing liquid, which would be forced into it on all sides by a pressure vastly greater than any known in our laboratories.

Even if we make the violent assumption that the sinking mass is a kilometre, or several kilometres, thick, it is difficult to see how it could continue its downward course, undissolved by temperature and pressure, below a depth approximating one-tenth of the radius, or 637 kilometres. The sinking would be quite slow, owing to stiffness of the fluid, and could hardly be accomplished to this depth inside of several days, or more probably weeks.

Moreover, before the mass reached a depth of 260 kilometres, or less than one-twentieth of the radius, the density of the molten fluid would become 20 per cent. greater than it was at the surface, owing to pressure; and when the solid mass was no denser than the surrounding fluid it would cease to sink. Or, if it had acquired a small velocity downward in the fall from the surface against the viscous resistance of the fluid, which is enormously increased by the eddy arising from the condition of continuity, it might go down a little lower until the motion was overcome by the buoyancy of the denser fluid below. Accordingly, so far as one can see, solidified crust in sinking could by no possibility go lower than one-tenth of the radius, which would hardly accomplish the building up of a solid nucleus.

In considering the effects of pressure in forcing molten fluid into the sinking solid, we have not assumed that the density would thereby be increased; for at the great temperature of the fluid it is obvious that the solid into which the hot liquid entered would be dissolved, and heat from the fluid would be conducted rapidly through the solid mass. Thus no cause seems to be overlooked which could invalidate our conclusion.

It rests primarily upon the enormous pressures known to exist at great depths in the earth, and their undeniable effect in forcing the molten fluid into any possible solid body, so as to prevent it attaining any considerable depth without dissolving; and upon the assumption that even molten rock under such forces would take approximately the density given by Laplace's law, which hardly admits of reasonable doubt.

In considering these questions heretofore, the hypothesis of incompressibility for the molten fluid has been tacitly implied or assumed. Whether such an hypothesis is justified will appear differently to different minds, but for our part we cannot hesitate in rejecting it on account of the known porosity of all matter, and its observed yielding and condensation under great forces.

On account of the difficulty in handling liquids, especially when at high temperatures, they have not been so carefully investigated in the laboratory as solids; but there remains scarcely any doubt that under planetary pressure they would all yield like sponges.

In indicating his interest in the paper on planetary pressures (*Astronomische Nachrichten*, No. 3992), one of the most eminent British mathematical physicists has pointed out that to his mind the present writer has underestimated the probability that the earth has a metallic nucleus. I have since pointed out in a letter to the editor of NATURE (April 13, p. 559) that pressure, and not metallic constitution, is the true physical cause of the earth's rigidity; for under such pressure any kind of matter would assume a hardness greater than that of steel; and as the material is above the critical temperature of every substance it is really gaseous, and would expand with incredible violence if the pressure could only be relieved.

In the *Astronomische Nachrichten*, No. 3992, I have shown that in any mass of considerable size, so condensed that the pressure amounts to millions of atmospheres, circulation at great depth becomes practically impossible, on account of the friction due to the increasing pressure as we descend within the mass. The pressure and friction which prevent circulation also prevent separation of the elements according to their densities. While it may not be possible to say that there is not an increasing amount of metals, such as iron, towards the centre of the earth, it is, I think, clear that there is no distinctively iron nucleus; for the existence of such a nucleus would imply that the earth's mass had unimpeded circulation when in a fluid state, all of which is to the last degree improbable.

When the earth was less condensed it was at lower temperature, and the elements may not have been fused; and as condensation advanced, and the temperature rose, the friction due to pressure operated with increasing intensity to destroy circulation, which would thus be restricted to the subsidence of compact masses decidedly denser than the surrounding fluid. As the fluid was necessarily at high temperature, a compact mass would soon be dissolved, and further circulation of its elements practically cease.

It seems, therefore, very difficult to escape the conclusion that the earth's interior is a magma of all the elements, the increasing density towards the centre being due primarily to pressure. If any separation of the metals from the rocks took place, it could only be near the surface where the pressure is slight; but because the rocks predominate at the surface, we must not conclude the same material does not exist abundantly in the great central nucleus of the globe.

The difference in the point of view here adopted and that held by the older school of physicists is based primarily upon the effects of pressure. While there is a certain disappointment in negative results, they are sometimes useful in leading us to new conceptions, and perhaps we may hope that further study of these difficult questions will produce results admitting of general acceptance. It should be added that the pressures for the interior of the earth, calculated in the *Astronomische Nachrichten*, No. 3992, would not be very greatly modified by any other admissible law of density.

The researches of Radau and Darwin (*cf. Monthly Notices*, Roy. Astron. Soc., December, 1899, pp. 122–3) have shown that, so far as the mathematical conditions are concerned, the law of density within the earth might depart considerably from that of Laplace. But on *physical grounds, including the incontestably steady rise of pressure towards the earth's centre, whatever be the exact law of density, and especially the observed yielding and condensation of all matter under such forces*, I hold that the true law is essentially that of Laplace, and any departure from it in the actual arrangement of the matter of the globe is likely to be extremely small and unimportant.

NOTES ON STONEHENGE.[1]

VI.—On the Solar Observations made in British Stone Circles.

In my last notes I referred to the star observations which might be made by means of stone circles. I now pass to solar observations.

I have already pointed out that much time has been lost in the investigation of our stone circles, for the reason that in many cases the exact relations of the monuments to the chief points of the horizon, and therefore to the place of sunrise at different times of the year, have not been considered; and when they were, the observations were made only with reference to the magnetic north, which is different at different places, and besides is always varying; few indeed have tried to get at the real astronomical conditions of the problem.

The first, I think, was Mr. Jonathan Otley, who in 1849 showed the "orientation" of the Keswick circle "according to the solar meridian," giving true solar bearings throughout the year.

Fig. 14.—Maeshowe, in the foreground, and the Stones of Stenness. From "Notice of Runic Inscriptions," by James Farrer, M.P. (1862).

I wrote a good deal in Nature[2] on sun and star temples in 1891, and Mr. Lewis the next year expressed the opinion that the British stone monuments, or some of them, were sun and star temples.

Mr. Magnus Spence, of Deerness, in Orkney, published a pamphlet, "Standing Stones and Maeshowe of Stenness,"[3] in 1894; it is a reprint of an article in the *Scottish Review*, October, 1893. Mr. Cursiter, F.S.A., of Kirkwall, in a letter to me dated March 15, 1894, a letter suggested by my "Dawn of Astronomy," which appeared in that year, and in which the articles which had been published in Nature in 1891 had been expanded, directed my attention to the pamphlet; the observations had no pretension to scientific accuracy, and some of the alignments are wrongly stated, but a possible solar connection was pointed out.

I began the consideration of the Stenness circles and alignments in 1901, but other pressing calls on my time then caused me to break off the inquiry. Quite recently it occurred to me that a complete study of the Stenness circles might throw light on the question of an earlier Stonehenge, so I have gone over the old papers, plotting the results on the Ordnance map.

Now that the inquiry is as complete as I can make it without spending some time in Orkney with a theodolite, I may say that in my opinion Mr. Spence's contention in his pamphlet on Maeshowe is confirmed, although many of the alignments to which he refers in support of it prove to be very different from those he supposed and drew on the map which accompanies his paper.

The alignments on which he chiefly depended were two, one running from the stone circle past the entrance of Maeshowe to the place of sunrise at Halloween (November 1), another from the same circle by the Barnhouse standing stone to the mid-winter sunrise at the solstice.

I give a copy of the Ordnance map showing the true orientation of these and of other sight lines I have made out. From this it will be seen that observations of the sun were provided for on the days in question, and that the circles and outstanding stones were undoubtedly set up to guide astronomical observations relating to the different times of the year. Of course, as I have shown elsewhere, such astronomical observations were always associated with religious celebrations of one kind or another, as the astronomer and the priest were one.

I shall not refer to all the sight lines indicated, but deal only with those, bearing upon the Stonehenge question, which I have without local knowledge been able to test and justify.

But first we must consider the astronomical differences between the rising of a star and of the sun, by which we mean that small part of the sun's limb first visible.

It is too frequently imagined that for determining the exact place of sunrise or sunset in connection with these ancient monuments we have to deal with the

[1] Continued from vol. lxxi. p. 538.
[2] See especially Nature, July 2, 1891, p. 201.
[3] Gardner: Paisley and London.

sun's centre, as we should do with the sun half risen. As a matter of fact, we must consider that part of the sun's limb which first makes its appearance above the horizon; the first glimpse of the upper limb of the sun is in question, say, when the visible limb is 2′ high.

shown that the half-way time between an equinox and a solstice is when the sun's centre has a declination approximately 16° N. or S. In Orkney, with the latitude of 59°, assuming a sea horizon, the amplitude of sunrise or sunset is 32° 21′, the corresponding azimuth being 57° 39′.

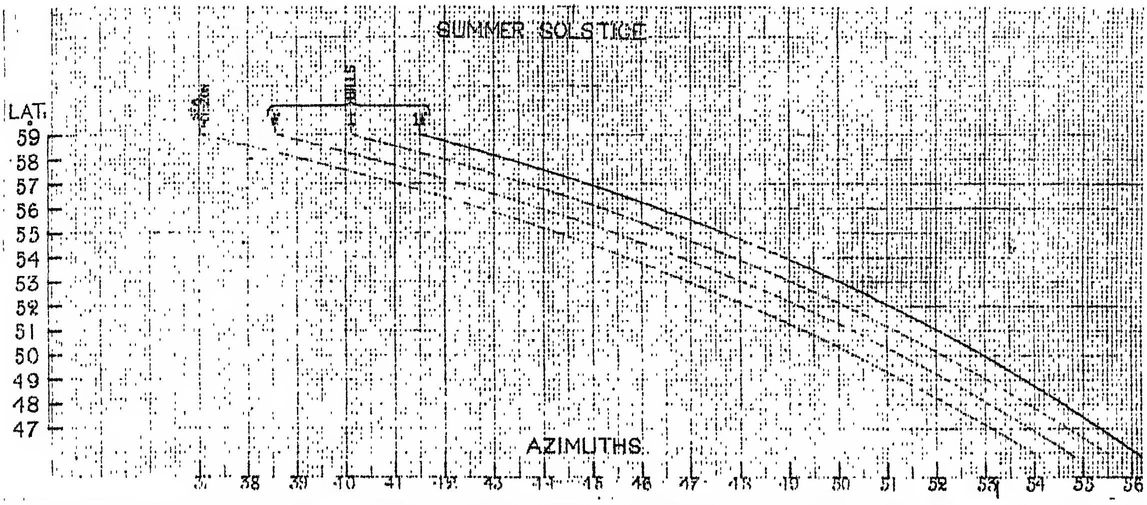

FIG. 15.—The Azimuths of the Sunrise (upper limb) at the Summer Solstice. The Values given in the table have been plotted, and the effect of the height of hills on the azimuth is shown.

To make this quite clear I give a table which has been computed by Mr. Rolston, of the Solar Physics Observatory, showing the true azimuth with hills up to 1½° high for lat. 59° N., the latitude of Stenness, and 51°, nearly the latitude of Stonehenge, of the sun's upper limb for the solstitial year.

SOLAR AZIMUTHS

	Lat. 59°	Lat. 51°
SUMMER SOLSTICE.	Rising N. of E. or Setting N. of W.	Rising N. of E. or Setting N. of W.
	° ′	° ′
1. Sun's centre; uncorrected ...	39 16	50 40
2. Upper limb; corrected for semi-diameter and refraction ...	37 1	49 20
3. ,, ,, ,, and hill ½° high ...	38 34	50 16
4. ,, ,, ,, ,, 1° ,, ...	40 8	51 12
5. ,, ,, ,, ,, 1½° ,, ...	41 30	52 4
WINTER SOLSTICE.	Rising S. of E. or Setting S. of W.	Rising S. of E. or Setting S. of W.
	° ′	° ′
1. Sun's centre; uncorrected ...	39 16	50 40
2. Upper limb; corrected for semi-diameter and refraction ...	41 24	52 0
3. ,, ,, ,, and hill ½° high ...	39 54	51 4
4. ,, ,, ,, ,, 1° ,, ...	38 23	50 8
5. ,, ,, ,, ,, 1½° ,, ...	36 54	49 14

Now the most interesting and best defined line with this azimuth on the Ordnance map is the one stretching S.E. from the centre of the Stenness circle to the Barnstone, with an azimuth of 57° 15′. The line contains between the two points I have named another stone, the Watchstone, 18½ feet high, in the precise alignment; and from the statements made and measures given it is to be inferred that a still more famous and perforated stone, the "Stone of Odin," demolished seventy years since, was also in the same line within the extremities named.

If we may accept this we learn something about perforated stones, and can understand most of the folk lore associated with them, and few have more connected with them than the one at Stenness. I suggest that the perforation, which was in this case 5 feet from the ground, was used by the astronomer-priest to view the sunrise in November over the Barnhouse stone in one direction, and the sunset in May over the circle in the other.

There is another echo of this fundamental line; that joining the Ring of Bookan and the Stones of Via has the same azimuth and doubtless served the same purpose for the May year.

But this line, giving us the May sunset and November sunrise, *not* the December solstitial sunrise as Mr. Spence shows it, is not the only orienta-

The first important thing we learn from the table is that although at any solstice the azimuths of the rising and setting of the sun's centre are the same, the azimuths of the upper limb at the summer and winter solstices differ in a high northern latitude by some 5°. The difference arises, of course, from the fact that the limb is some 16′ from the sun's centre, so that considering the sun's centre as a star with fixed declination, at rising the limb appears before the centre, and at setting it lags behind it.

It will also be seen that at sunrise hills increase the azimuth from N., and refraction reduces it; while at setting, hills reduce the azimuth from S. and refraction increases it.

Not only does calculation prove the worship of the May and June years, but I think the facts now before us really go to show that in Orkney the May year was the first established, and that the solstitial (June) year came afterwards, and this was the chief question I had in view.

I will begin with the May year. I have already

tion connected with the May year at the stones of Stenness. The November sunset is provided for by a sight-line from the circle to a stone across the Loch of Stenness with an azimuth of S. 53° 30′ W.

To apply the table to the solstitial risings and settings at Stenness, and the sight-lines which I have plotted on the map, it will be seen that the table shows us that the lines marked

N. 39° 30′ E.	S. 41° 0′ E.
N. 41° 16′ E.	S. 36° 30′ W.

are solstitial lines; to get exact agreement with the table the heights of the hills must be found and allowed for. I have roughly determined this height from the 1-inch map in the case of the Barnstone-Maeshowe alignment.

On the N.E. horizon are the Burrien Hills, four miles away, 600 feet high at the sunrise place, gradually ascending to the E., vertical angle = 1° 36′ 30″. The near alignment is on and over the centre of Maeshowe. Colonel Johnston, the Director-general of the Ordnance Survey, has informed me that the true azimuth of this bearing is N. 41° 16′ E., and in all probability it represents the place of sunrise as seen from the Barnstone when Maeshowe was erected. What is most required in Orkney now is that some one with a good 6-inch theodolite should observe the sun's place of rising and the angular height of the hills at the next summer solstice in order to determine the date of the erection of Maeshowe. Mr. Spence and others made an attempt to determine this value with a sextant in 1899, but not from the Barnstone.

The Ordnance maps give no indication of stones, &c., by which the direction of the midsummer setting or the midwinter rising and setting might have been indicated from either the Maeshowe or the Barnstone.

To sum up the solar alignments from the circle.

We have the May sunrise marked by the top of Burrien Hill, from 600 to 700 feet high, Az. 59° 30′.

We have the November sunset marked by a standing stone on the other side of the Loch of Stenness, Az. 53° 30′.

June rising, Az. true 39°. The top of Hindera field, more than 500 feet high, the highest peak, triangulation station.

December rising, tumulus (Az. 41°) on Ward Hill.

December setting, tumulus Onston 36° 30′.

General Remarks.

It is not a little remarkable that the winter solstice rising and setting seem to have been provided for at the Stenness circle by alignment on the centres of two tumuli across the Loch, one the Onston tumulus to the S.W. (Az. 36° 30′), the other tumulus being on Ward Hill to the S.E., Az. 41° (rough measurement).

It looks also very much as if the Maeshow tumulus was an after structure to use the Barnstone for the summer solstice rising; then these two other tumuli, to deal with the winter solstice at Stenness circle, may have been added at the same time. All these provided for a new cult.

There are also tumuli near the line (which cannot be exactly determined because the heights of the hills are unknown) of the summer solstice setting; none was required for the sunrise at this date, as the line passes over the highest point of Hindera field, a natural tumulus more than 500 feet high, and on that account a triangulation station.

Another argument in favour of the tumuli being additions to the original design is that the place of the *November* setting from the Stenness circle is marked, *not* by a tumulus, but by a standing stone. As the stone near Deepdale and the tumulus at Onston are only about 1200 yards apart, the suggestion may be made that in later times tumuli in some cases replaced stones as collimation marks.

NORMAN LOCKYER.

SOUTH AFRICAN GEOLOGY.[1]

MR. ROGERS has produced a handbook to the geology of Cape Colony which is sure to remain a standard treatise. New observations will be recorded in future editions, as the work of his survey is carried on; but results made public as recently as 1904 are included in the present volume. The book appears with especial appropriateness, now that the visit of the British Association to South Africa has been officially organised; and the included geological map, on the scale of about one inch to ninety miles, gives an admirable impression of the country. In it we see the huge Karroo synclinal, occupying almost all the colony, and lying between the pre-Devonian masses that crop out upon the north and the closely folded rocks of the Cape system along the south; while Mr. Rogers's introduction connects the scenic features with the geological structure in a manner that attracts us at the outset.

It is unfortunate that the names chosen for the colonial systems of rocks are not readily represented by adjectives. Hence such ungrammatical expressions as "pre-Cape" and "pre-Karroo" have been received indelibly into literature. Even the International Congress may hesitate to speak of an "*étage bokkeveldien*," though we have, to be sure, "purbeckien" and "bathonien" in Europe. This use of local names is, of course, greatly to be commended, in view of the scarcity of fossils in the great majority of the series.

The invasion of the old Malmesbury beds in the west of the colony by granite is concisely described on p. 38; and it is interesting to note how gneissic structures have arisen in the granite, as in so many other instances, without "evidence of a great amount of crushing or rearrangement of its component minerals after it solidified." The foliation-planes in the gneissoid granite are parallel with the strike and cleavage of the adjacent sedimentary rocks, and the whole structure seems one of subterranean flow. The granulites of the Darling area will clearly bear comparison with those that have been so much discussed in Saxony. The intercalation of orthoclase crystals from the granite in lenticular areas between laminæ of slate (p. 43) reminds us, again, of the composite rocks of Donegal.

Mr. Rogers gives an interesting account of the stages in the passage from the well known blue crocidolite to the more siliceous yellow "griqualandite" in the slates of the Griquatown series. The slates themselves are converted into jasper-rocks where the most altered amphibole occurs; and the crests and troughs of the folds have afforded hollows in which the fibres of amphibole have crystallised across from one surface to another.

The Cape system, including the Table Mountain series at its base, has been greatly contorted and overfolded in the south; but the southern edge of the Karroo beds is also involved (p. 407), and the great east-and-west ridges of the continental margin date from somewhere about Jurassic times. Flattened and striated pebbles occur in the Table Mountain beds, and are regarded as the first evidence of a neighbouring highland on which glaciers gathered. The Devonian Bokkeveld beds follow, and the still higher and famous Dwyka conglomerate is, as all geologists know, of Permo-Carboniferous age. It is somewhat fascinating to conceive the growth of glacial conditions through at least two long geological periods, until the flood of ice at last spread southward from the Transvaal territories, and scored and rounded all the preceding rock-masses down to the region of the Cape itself.

The Dwyka beds, a facies of the Kimberley-Ecca series, and long regarded as volcanic tuffs, are here

FIG. 1.—Overfolded quartzites of the Table Mountain Series, Meiring's Poort, representative of the great upheaval, which probably took place in early Jurassic times. From Rogers's "Geology of Cape Colony."

very adequately described, with several effective illustrations. The glacial series at Vereeniging is associated with beds containing the Glossopteris flora, and also Sigillaria and other northern forms; and Mr. Rogers points out that the cold cannot have been responsible for preventing a more frequent mingling of these two well marked floras. The most novel portion of the account of the reptiliferous Beaufort beds of the "Karroo system" is the strong hint (p. 198) that they should be regarded as Permian rather than Triassic. This view, based on Amalitzky's work in Russia, would lead to a reconsideration of the Elgin Sandstone also, and to the acceptance of a development of reptilian life in Permian

[1] "An Introduction to the Geology of Cape Colony." By A. W. Rogers, M.A., F.G.S., Director of the Geological Survey of Cape Colony. Pp. xviii+463. (London: Longmans, Green and Co., 1905.) Price 9s. net.

times as surprising and swiftly various as that of the Eocene Mammalia. We presume that the Stormberg series must then include the whole of the Trias, and not merely the Rhætic, as Feistmantel and Seward have proposed. The consideration of this and similar questions is made far more interesting by the appearance of Dr. Corstorphine's address on the history of stratigraphical investigation in South Africa ("Report of the South African Association for the Advancement of Science," 1904, p. 145), to which is appended a table showing the classifications of various authors, starting with the brilliant and perceptive work of Bain in 1856.

Prof. R. Broom has provided Mr. Rogers with a chapter on the Karroo reptiles, in which the early carnivorous types, Ælurosaurus, Lycosuchus, &c., are separated from the Theriodonts as "Therocephalia." The pose given to the skeleton of Pareiasaurus in Fig. 18 is more erect than that at present adopted in the British Museum. The well known work of Prof. H. G. Seeley is mentioned later in the bibliographical appendix.

Mr. Rogers, quoting the view of Mr. Kitchin, who compares the fossils with those of similar beds in India, does not allow the presence of Jurassic strata in the Uitenhage series, so that the Jurassic system may be represented merely by the underlying unconformity (compare p. 408). The perforation of the Stormberg and preceding rocks by the diamantiferous volcanic pipes occurred, in all likelihood, in Lower Cretaceous times. The bending up of the strata round these vents presents us with a curious reminder of the old "crater of elevation" theory.

Denudation has attacked the surface of the interior of the colony "uninterruptedly from the close of the Stormberg period (Rhætic) to the present day," and the folded belt of the south seems to have furnished a fairly complete barrier against inroads of the Cretaceous sea (p. 414). A useful chapter on the geological features to be observed along the main lines of railway concludes this compact and highly attractive handbook. GRENVILLE A. J. COLE.

THE NAUMANN FESTIVAL AT CÖTHEN.

NAUMANN is but a name to nine out of ten British ornithologists, and the proportion of them who have held in hand a volume with that name on the title-page must be smaller still. Yet it was borne by two men who, taking them all round, were the most practical ornithologists that ever lived, for their personal knowledge of the birds of Central Europe was not exceeded by that of any of their contemporaries, and it may be fairly doubted whether any of their successors, vastly improved as are the modern means of acquiring such knowledge, have attained to the like acquaintance.

The elder Naumann, Johann Andreas, seems hardly ever to have quitted the little village of Ziebigk, near Cöthen, in the duchy of Anhalt, where he was born in 1744, the son of a small landed proprietor, to whose estate he succeeded. He has left a curious autobiographical sketch, which was prefixed to the first volume of the edition of the joint work of himself and his son, Johann Friedrich, published in 1822. If ever a man devoted himself to the observation and study of birds it was this Johann Andreas, who from his boyhood passed days and nights in this sole pursuit. How he found time to take a wife—for he tells us that he often forgot his dinner—is marvellous; but marry he did, and had three sons, the eldest, Johann Friedrich, already named, born in 1780, and two others; one of them, Carl Andreas, born in 1786, became a fair assistant to his father and brother, without, however, publishing anything on his own account. The father brought up these three boys to follow his own tastes and live his own life. A gun was put into their hands as soon as they could hold it, they were made familiar with every device for catching birds, and they were also taught to draw. In this last respect the eldest attained so much proficiency that by the time he was fifteen he had executed a great number of drawings of birds, which the father proceeded to have engraved on copper and to publish in folio form. The work thus produced proves to be one of the rarest in ornithological literature, if literature it may be called, seeing that not a word of letterpress accompanied the plates. Whether a complete set of them exists anywhere is uncertain, and Dr. Leverkühn's labours seem to show that not quite a dozen more or less imperfect copies are known, though there is no room here for bibliographical details. The next thing the father did was to bring out in small octavo the first volume of what was called "A Detailed Description of the Forest-, Field-, and Water-birds of the Principality of Anhalt and the Neighbouring Districts." This appeared in 1797, and was illustrated by coloured figures by the son Johann Friedrich. Some of them are reproductions of those in the older series, but the style of drawing was manifestly improved, and, moreover, went on improving as the work itself did, for it quite outgrew the bounds of its native principality, and the fourth and last volume, published in 1803, appeared as "The Natural History of the Land- and Water-birds of Northern Germany and the Adjoining Countries." This was followed by a series of eight supplements, the last of which came out in 1817. A remarkable feature of this work is its extreme simplicity and truth, and the absence of all scientific pretence. There is not even a Latin name in it! Yet there was no attempt by "writing down" to gain popularity, and whether it became popular is doubtful. All that can be said is that copies are now not easily to be had. In England when a man tries to do a thing of this kind we know too well what is generally the lamentable result. He makes a fool of himself on almost every page; but this is just what Johann Andreas did not. He wrote with quiet dignity from his own knowledge, and his knowledge was sound. There was no need for him to borrow from anybody else.

The father's work being thus successfully concluded, the son, Johann Friedrich, lost no time in bringing out a new edition of it, and it is on this edition that the latter's fame rests, and rests securely. The preface is dated 1818, and some copies of the first volume are said to bear 1820 on the title-page. Doubtless it was then ready for publication, though for some reason it seems to have been delayed for a couple of years. Twelve volumes (parts they are called) appeared at long intervals, the last in 1844, and it may be truly averred that for completeness nothing like them exists in any language. They continue the same simple and direct style of the father's work; but the son willingly cited other authors and showed that he had read them. He also extended his area of observation, journeying to Jutland in the north and to Hungary in the south, beside voyaging to Heligoland—the ornithological peculiarities of which he was the first to detect. Moreover, he discovered that anatomy was not to be neglected, and accordingly each genus as he treated of it had prefixed to it a brief account of its internal structure, and to this end he had the good fortune to obtain the services of Christian Ludwig Nitzsch, who carried on this portion of the work until his death in 1837, when his place was taken by Rudolf Wagner. Two years after the work was ended the author began a supplement, which had not proceeded far when he died, in 1857, and this was left to be completed by two of his friends, the late Prof. J. H. Blasius and Dr. Eduard Baldamus.

Carefully elaborated as this great work had been, its information had, of course, fallen behind the times, and

a natural desire was expressed for a new edition. The first part of this appeared in 1897, under the general editorship of Dr. Carl R. Hennicke, of Gera, who has been assisted by a company of thirty-six coadjutors, comprising the chief ornithologists of Central Europe, and to celebrate the recent completion of this grand undertaking in ten folio volumes a *Naumann-Feier* is to be held at Cöthen on Sunday, May 14, under the direction of Dr. Jacobi von Wangelin, of Merseburg, and Prof. Rudolf Blasius, of Brunswick, the presidents respectively of the German Bird Protection Union and the German Ornithological Society. The business of the day is announced as of the simplest character, just as one may suppose would be consonant with the wishes of the men to be honoured—an inspection of the Naumann collections, now housed in the ducal palace, a pilgrimage to the graves of the Naumanns at Ziebigk, their old abode, on which a laurel wreath will be laid, and a visit of respect to the daughter-in-law of Johann Friedrich, a return to Cöthen for a festival dinner—that is all. Who will attend I know not, but assuredly every German ornithologist will be present in the spirit, and my chief object in writing these lines is that British ornithologists should sympathise with their German brethren on the occasion. Making every allowance for the ordinary Englishman's linguistic deficiencies, it is not to the credit of our predecessors in this country, though there are many of whom we may be justly proud, that until the year 1850 not one of them seems ever to have heard of the Naumanns and their incomparable works. It was Mr. G. R. Gray who, in a British Museum catalogue, first cited that of Johann Friedrich, and then merely on nomenclatural grounds. It was there that I first met with its title, and I lost no time in seeking the work in the library of Cambridge University. Words fail me to express the delight with which I looked into one volume after another of this huge store of information, or the admiration with which I regarded its unpretentious but exquisitely executed plates. That was nearly five-and-fifty years ago, but much as the study has since advanced, the opinion I then formed I hold now, that for fulness of treatment, perspicuity, and general accuracy, the work of Johann Friedrich Naumann has not been surpassed.

Willingly would I dwell longer on the subject, but I think I may have said enough, though I must add that for many of the details above given I am indebted to two articles by Dr. Lindner published in "Die Schwalbe" of Vienna for 1894 (Nos. 7 and 8), and still more to Dr. Paul Leverkühn's excellent biographical preface to the first volume of the recent edition already mentioned, which has been separately printed, "Biographisches über die Drei Naumanns" (Gera-Untermhaus: 1904). Later still that gentleman has come into possession of much of Johann Friedrich's correspondence, which it is sincerely to be hoped he will find the means of publishing, as it can hardly fail to be of great interest.

ALFRED NEWTON.

DR. J. E. DUTTON.

IT is with deep regret that we announce the sudden death of Dr. Dutton (Walter Myers Fellow) at Kosongo, in the Congo, on February 27, while actively engaged in the investigation of trypanosomiasis and tick fever.

The expedition which Dr. Dutton was leading was a very completely equipped one, and commenced work in the Congo in September, 1903. It consisted originally of Drs. Dutton, Todd, and Christy, and was subsequently joined by Dr. Inge Heiberg. The Belgian Government erected a special hospital for them, and placed every possible facility at their disposal both for investigation and travelling. Whilst conducting the investigation and mapping the distribution of sleeping sickness and tick fever, they travelled several thousand miles by river and road, and reached a station beyond Stanley Falls.

In the death of Dr. Dutton, not only have the Tropical School and the University of Liverpool lost a brilliant graduate, but medicine has lost one of its most promising men, a man who, although only twenty-nine years of age, had already won a recognised position throughout the scientific world. Educated at the King's School, Chester, Dr. Dutton proceeded to the University of Liverpool, where he rapidly made his way to the front. In 1897 he was appointed to the George Holt fellowship in pathology, a post which has had a marked effect in stimulating men to devote time to research and in supplying able investigators in tropical medicine. In 1900 he commenced the study of tropical medicine under the leadership of Dr. Annett, and together with Dr. Elliott, of Toronto University, he proceeded to Nigeria in order to study the habits of the Anopheles and the most effective measures of prevention of malaria. In 1901 he proceeded alone to the Gambia, and drew a comprehensive and useful anti-malarial report which has proved of the greatest service to the colony. It was during this expedition that he identified in the blood of the patient shown to him by Dr. Forde, of Bathurst, the trypanosome which he described and named as *Trypanosoma gambiense*.

Having established the presence of the trypanosome in man, Dr. Dutton immediately set off on another expedition to ascertain how far it was distributed in the native population. This expedition formed the basis of his first trypanosomiasis report (Senegambia, 1902).

The first progress report of the Congo expedition was published in 1904; this has been followed by others, including the description of the "Congo Floor Maggot," by Drs. Dutton, Todd, and Christy, and the "Cerebro-spinal Fluid in Trypanosomiasis," by Dr. Christy; "A Comparison of the Animal Reactions of the Trypanosomes of Uganda and Congo Free State Sleeping Sickness with that of *Trypanosoma gambiense*," by Drs. Thomas and Linton; "Two Cases of Trypanosomiasis in Europeans," by Drs. Dutton, Todd, and Christy; and "Supplementary Notes on the Tsetse-flies," by Mr. E. E. Austen. More recently Dr. Dutton wrote an interesting paper on the "Intermediary Host of the *Filaria cypseli*" (the filaria of the African swift), in which he described the intermediate host as a louse (subfamily Leiothinæ) in the abdominal cavity of which he observed the various stages of the development of the filaria. He showed that the infection was probably spread by the birds eating the infected lice.

Toward the end of 1904 the investigators had reached Stanley Falls, and quite independently Drs. Dutton and Todd verified the discovery of the cause of tick spirillum fever in man made a few weeks previously by Milne and Ross in the Uganda Protectorate; but, furthermore, they were able to transmit the disease to monkeys and rabbits by means of the bite of the infected tick. They were able to make *post mortem* examinations on cases of the fever, in the course of which Dr. Dutton contracted the disease by a *post mortem* wound and Dr. Todd an abortive attack apparently directly through a tick bite. From this fever they recovered, in Dr. Dutton's case after four typical relapses. Their researches into the relationship between the infection in man and the tick were so far advanced that they were able to prepare a report which is due by the next mail. In the meantime, they have given an account of an experiment in which tick spirillum fever has been conveyed to a monkey by the bites of young ticks during the first feed after hatching from the ova of naturally infected adults.

NOTES.

THE gentlemen's soirée of the Royal Society will take place at Burlington House on Wednesday next, May 17.

IN a murder trial concluded last week, a finger mark left by one of the prisoners upon a cash-box tray at the shop where the crime was committed was used for purposes of identification. An inspector gave evidence that there were 80,000 or 90,000 sets of finger prints in the finger print department of Scotland Yard, and that he had never found two such impressions to correspond. The right thumb print of one of the prisoners agreed in twelve characteristics with an impression made with perspiration upon the cash-box tray, and therefore gave corroborative evidence of identity. It is probable, as Mr. Galton pointed out some years ago, that no two finger-prints in the whole world are so alike that an expert would fail to distinguish between them. The system was largely used in India by Sir William Herschel nearly fifty years ago, and was found by him to be most successful in preventing personation, and in putting an end to disputes about the authenticity of deeds. He described his methods in these pages in 1880 (vol. xxiii. p. 76); and in the previous volume (vol. xxii. p. 605) Mr. Henry Faulds referred to the use of finger-marks for the identification of criminals. There is no doubt as to the value of this system of identification, which was described in the pages of NATURE long before its practical applications had been realised, and we regret that anything should have occurred to throw discredit upon it. It appears from the reports of the trial referred to that a person who professed to be properly qualified wrote to the Director of Public Prosecutions, and also to the solicitors for the defence, offering to give evidence as an expert on the finger impressions, although he had not seen the impressions. It is not to be wondered at that Mr. Justice Channell should denounce such action in strong language, and whether the jury agreed with him or not—that the witness was "absolutely untrustworthy"—they no doubt considered that evidence which could be given on either side could not be of much importance. From the scientific point of view, we regret that a method which is associated with the names of men of such scientific eminence as Sir William Herschel and Mr. Francis Galton should be brought into disrepute. Finger prints are not only of value for personal identification, but also for hereditary investigations, and any action which produces comments like those made by Mr. Justice Channell is to be deplored, because it tends to shake the confidence of men in methods which rest on secure scientific foundations.

THE council of the Linnean Society of New South Wales has appointed Mr. Harald I. Jensen to be the first Linnean Macleay fellow.

THE *Athenaeum* announces the death of Prof. Otto Struve, who succeeded his father as director of the Nicholas Central Observatory at Pulkowa in 1861.

Science announces that Prof. L. Warren, for twenty-seven years professor of mathematics at Colby College, died on April 21, at the age of sixty-nine years.

THE *Times* understands that the trustees of the British Museum have expressed their willingness to receive carefully selected phonographic records of the voices of distinguished living men. The records will be for posterity only, and will in no circumstances be available for contemporary use.

PROF. E. B. FROST has been appointed director of the Yerkes Observatory by the trustees of the University of Chicago, in succession to Prof. G. E. Hale, who now gives his whole time to the establishment of the new Solar Observatory of the Carnegie Institution at Mt. Wilson, California.

A PARTY of zoological students from the Birkbeck College spent part of the Easter vacation trawling, dredging, and shore collecting at West Mersea, on the Essex coast. Although the temperature was very low for the time of year, many specimens were collected, and much experience was gained.

A REUTER correspondent at Bombay reports that a severe earthquake occurred at Bandar Abbas on April 25. Five shocks were experienced during the afternoon, and shocks have been occurring daily since. Sarn, a town west of Bandar Abbas, is reported to have suffered severely.

THE death is announced, in his eighty-eighth year, of Colonel N. Pike, known for his contributions to the natural history of birds, reptiles, and amphibia. For several years Colonel Pike held the post of American consul in the Island of Mauritius, and during this time he collected extensively the local fauna and prepared from the living specimens many coloured drawings. His most extended work was his "Sub-Tropical Rambles in the Land of the Aphanopteryx."

A REUTER telegram from Christiania reports that the *Belgica*, with the members of the Duc d'Orléans's Arctic Expedition on board, left Sandefjord on May 6 for Bergen, where the duke will embark. From Bergen the *Belgica* will go to Spitsbergen, Greenland, and Shannon Islands, where the Duc d'Orléans intends to visit the depôts of the Ziegler Expedition. His intention is to bring the members of that expedition back with him on the *Belgica*, and he hopes to return to Ostend in September.

THE Rome correspondent of the *Pall Mall Gazette* states that it is again proposed to affix a marble tablet to the Villa Medici, which is French property, to remind passers by and posterity that Galileo was kept prisoner there from June 24 to July 6, 1633. Italy has already erected a small monument to Galileo at the very door of the villa, with the following inscription:—"The neighbouring palace, which belonged to the Medici, was the prison of Galileo Galilei, guilty of having seen the earth revolving round the sun."

THE anniversary meeting of the Royal Geographical Society will be held on Monday, May 22. The annual conversazione will be held in the Natural History Museum, South Kensington, on Tuesday, June 27. In place of the annual dinner of the society this year, a banquet in honour of the retiring president, Sir Clements R. Markham, K.C.B., will be held on the evening of the anniversary meeting, May 22, at the Hotel Metropole.

THE Paris correspondent of the *Times* remarks that about 150 physicians and surgeons have arrived there from England, many of them with their wives and families, to return the visit which the French doctors paid to London last year. The formal reception took place last night at the Sorbonne. During the stay of the English medical men, besides the many attractive excursions and social entertainments arranged in their honour, every facility is to be given them for inspecting the hospitals.

IN proposing the toast of "The Japan Society" at its annual dinner on May 3, Sir Frederick Treves referred to the medical and surgical ability of the Japanese. Nothing

astounded him more, he said, in his recent visit to Japan than the way in which the Japanese have inquired into the medicine and surgery of the western world and the marvellous thing they are making out of it. It is difficult to credit the astonishing advance made by the Japanese in medical equipment in time of war. Many of the problems which have been the terror of war in European countries the Japanese are solving or have solved. British troops enter a war with many determinations—one of which is to have 10 per cent. of sick, and they get it. The Japanese are quite content with 1 per cent. of sick, and they get it. The Japanese have all the qualities of a surgeon. They have infinite patience and infinite tenderness. Sir F. Treves is confident that not many years hence there will be seen in Japan one of the most progressive schools of medicine the world has ever known.

THE annual congress of the South-eastern Union of Scientific Societies will be held at Reigate on June 7–10 inclusive, under the presidency of Prof. Flinders Petrie, F.R.S. Among the papers to be contributed are the following:—"Mendel's Law," Miss Saunders; "Botany of Reigate District," Messrs. R. H. Welchman and C. E. Salmon; "Local Orchids," Dr. Hodgson; "Eggs of Lepidoptera," Mr. Tonge; "The Law of Treasure Trove in Relation to Archæological Research," Dr. William Martin; "The Land and Fresh-water Shells of S.E. England," Mr. A. Santer Kennard. There will be excursions to Worth Church; Gatton; Mr. Maw's observatory, Outwood; Reigate Castle; Mr. Brown's Atherfield clay pit, &c. The Mayor of Reigate will give a reception on Friday, June 9. The congress secretaries are Mr. G. E. Frisby, Redhill, and Mrs. Taylor, Clear's Corner, Reigate, from whom all information can be obtained.

DURING the forthcoming eclipse of the sun, on August 30, aëronautical ascents will be made at Paris, Burgos, Prague, and very likely in Algeria. It is intended to study the variations, not only of the temperature of the air in the shade and in the sun, but also the solar radiation at several altitudes. If it is possible to take aërial photographs of the corona from the balloons it will be done at Burgos, and possibly at Wargia. M. Trépied, director of the Algiers Observatory, has left for Guelma, on a railway 36 miles south-west of Bona, and really a desert oasis. The sky is anticipated to be quite clear at that place, as at the end of August northerly breezes, which are very frequent on the coast, are hardly to be felt in the Sahara. The Algerian eclipse observatory will be housed in the French public school. For the last twenty years a weather bureau has been established in Algeria, and is situated on the terrace of the City Hall. The establishment is connected by telegraph with forty stations, which are sending regularly each morning observations used in the reduction of the warnings and forecasts.

LORD AVEBURY delivered his presidential address at the soirée of the Selborne Society on May 3. In the course of his remarks he referred to the animated discussion which took place recently in the newspapers as to whether Greek should be a compulsory subject in university examinations —which is euphemistically termed "maintaining the Greek basis of education against the material tendencies of the present day." It is not we, he continued, who wish to pit Greek grammar against nature-study. Greek—even a little Greek—is very useful. But nothing was said, Lord Avebury contended, about science being a compulsory subject—which alike from a practical and an educational point of view is even more important. Education without science is incomplete and one-sided, and the greatest classical scholar, if he know nothing of the world we live in, is but a half-educated man after all. Sir James Crichton Browne spoke of the value of the society's work from the point of view of mental health, while Sir John Cockburn urged the usefulness of that study of nature which is not rigidly scientific. Among the many exhibits of natural history and antiquarian interest was some honey gathered by bees in the "East End." This was shown by the Stepney Borough Museum, and it is practically certain that it was derived from sugar on the ships in the London Docks, a mile from the hive.

THE Belgian Royal Academy has issued the following lists of prize subjects for 1905 and 1906:—for 1905, in mathematical and physical sciences, on the combinations formed by halogens; on physical, particularly thermal, phenomena accompanying dissolution; on linear complexes of the third order; and on the deviation of the vertical treated from the hypothesis of the non-coincidence of the centres of mass of the earth's crust and nucleus. In natural sciences, on the function of albuminoids in nutrition; on the reproduction and sexuality of Dicyemidæ; on the silicates of Belgium; on the formations of Brabant between the Bruxellian and the Tongrian; on certain Belgian deposits of sand, clay, and pebbles; on the sexuality of the individuals resulting from a single ovum in certain diœcious plants; and on the development of Amphioxus. For 1906 the subjects in mathematical and physical sciences are:—on critical phenomena in physics; on n-linear forms ($n>3$); on thermal conductivity of liquids and solutions; and on the unipolar induction of Weber. In natural sciences, on the Cambrian series of Stavelot; on the effect of mineral substances on the assimilation of carbon by organisms; on the effects of osmotic pressure in animal life; on the tectonic of Brabant; on the soluble ferments of milk; and on the physiological action of histones. The essays for 1905 and 1906 are to be sent in by August 1 of the respective years, and the prizes range from 24*l.* to 40*l.* in value. In addition, prizes bequeathed by Edward Mailly and in memory of Louis Melsens are offered under the usual conditions for astronomy and applied chemistry or physics respectively.

THE codling-moth forms the subject of *Bulletin* No. 222 issued by the entomological division of the Michigan Agricultural College Experiment Station. This insect is a serious enemy to fruit-growers in the district, and the author, Mr. R. H. Pettit, has carefully worked out its life-history and devised effective means for its destruction.

AT the first congress of the Association of Economic Biologists, held in Birmingham University on April 19–20, Mr. A. E. Shipley directed attention to the circumstance that bacteriological and parasitical science is unrepresented on the committee appointed by Parliament to inquire into the nature of grouse-disease. The president, Mr. F. V. Theobald, emphasised the importance of closer study of the aphids affecting cultivated plants in this country, while parasites in the liver of swine, the porosity of wood, the injuries inflicted on plants by spring-tails, and ticks and fleas as conveyers of disease formed the subjects of other communications.

ARTICLE No. 4 of vol. xx. of the *Journal of the College of Science of Tokyo University* is devoted to the description of the spoon-worms (Gephyrea) of Japan, and is illustrated by one coloured and three black and white plates. The author, Mr. I. Ikeda, states that hitherto only four species of these worms appear to have been recorded from

Japanese waters, and of one of these no specimens have come under his notice. From a study extending over several years, he has been enabled to add 34 additional species to the fauna, thus bringing the number up to 38. Of the 34, no less than 24 appear to be new forms, all of which are provisionally referred to previously known generic types, although there are grounds for considering that some of those included in Thalassema might advantageously be assigned to a new genus.

SOME excellent photographs of Australian bird-life are reproduced in the March number of the *Victorian Naturalist*, among which may be specially mentioned a group of young diamond-birds (Pardalotes) and a nestling bronze-cuckoo in the act of ejecting the rightful occupant of the nest in which it was hatched. "When discovered, the nest contained two young birds. The cuckoo, blind, featherless, and apparently not more than a day old, struggling till it got beneath its victim, gradually lifted it to the edge of the nest, resting at intervals, all the while balancing the resisting nestling in the hollow between the wings immediately at the back of the neck. Slowly and relentlessly it pushed the unfortunate wren over the side. . . . The young wren was replaced in the nest half a dozen times, but always with a like result until the cuckoo was thoroughly exhausted."

Two interesting Antarctic organisms obtained during the *Scotia* Expedition are described in the *Proceedings of the Royal Physical Society of Edinburgh*, vol. xvi., No. 2. In the first article, by Dr. J. Rennie, are discussed a number of isolated tentacles of a zoophyte belonging to the group Siphonophora. The specimens are barely sufficient for definite identification, but appear to indicate a type allied to the Mediterranean Apolemia, which attains a length of two or three yards. Mr. T. V. Hodgson, in the second communication, describes a five-limbed sea-spider (Pycnogonida) distinct from *Pentanymphon antarcticum* recently described on the evidence of a *Discovery* specimen. With the assistance of Dr. Calman, of the British Museum, the author has been enabled to identify the *Scotia* pycnogonid with *Decalopoda australis*, an almost forgotten generic type described so long ago as 1837. The occurrence of two five-limbed pycnogonids in the Antarctic is, in view of the absence of this type from all other seas, very remarkable.

MR. F. FLETCHER, Deputy Director of Agriculture, Bombay Presidency, is the author of a small volume, published at Bombay, entitled "Notes on some Egyptian Insect Pests." In the autumn of 1901 the author, it appears, was engaged to teach agricultural entomology to the students at the Khedivial Agricultural School, Giza, and found himself seriously hampered in his task by the fact that practically nothing was known with regard to the insects which are harmful to the Egyptian agriculturist. Accordingly, during a two years' sojourn in the country, Mr. Fletcher set himself to study such insects whenever opportunity occurred, and the present "booklet" is the result. It contains an introduction showing the position of insects in the animal kingdom, followed by a short summary of the life-history and structure of insects in general, after which comes an account of the species forming the proper subject of the "notes." The publication seems admirably adapted to the needs of those for whom it is intended.

THE catalogue forming appendix ii. to the *Kew Bulletin* of books and pamphlets added to the library of the Botanic Gardens during the past year has been received; as usual, the printing is confined to one side of the paper only, in order that, if desired, the separate titles may be cut out.

THE collection of phenological records by teachers and pupils of schools in Nova Scotia has been proceeding for some years, and the number of schools sending in lists has been increasing. The data supplied by about 300 selected schedules in 1903 have been utilised for the compilation of phenochrons or average dates for different regions of the province, and these have been tabulated in vol. x., part xvi., of the *Transactions of the Royal Society of Canada*.

SINCE the year 1900, a gooseberry mildew, *Sphaerotheca mors-uvae*, which appears to have been introduced from the United States, has been observed in Ireland and Russia. Mr. E. S. Salmon, who reported the first appearance in Ireland, and has since notified the spread of the disease, announces in the *Journal of the Royal Horticultural Society* (vol. xxix.) its continued increase in these countries. The yellow varieties seem to suffer most. Spraying checks the fungus, but the only effectual remedy is to burn all the diseased bushes. Mr. Salmon contributes also to *Annales Mycologici* an account of a disease observed on plants of *Euonymus japonicus* in the south of England and elsewhere caused by an *oidium* or conidial stage of one of the Erysiphaceæ.

HERR PAUL GROSSER has recently visited and described the site of the Tarawera eruption of 1886, in the north island of New Zealand ("Vulkanologische Streifzüge im Maoriland," *Verhandlungen des naturhistorischen Vereins der preuss. Rheinlande*, 1904, pp. 37–58). He lays stress on the linear grouping of the eruptive centres, the ash-cones of which are almost as contiguous as pearls on a string. A fine photograph is given of a crater exploded through rhyolite on Ruawahia, with basaltic ashes covering the country above. Incidentally, Herr Grosser examined the ground affected by the Port Nicholson earthquake of 1855, which is described in the later editions of Lyell's "Principles of Geology"; and he adds the interesting detail that the elevation of the floor of a lagoon by two metres enabled it to be successfully drained into the sea, a work previously attempted, but abandoned.

THE shoal-water deposits of the Bermuda banks are described by Mr. H. B. Bigelow (*Proc. Amer. Acad. Arts and Sciences*, xl., No. 15). The oceanic character of Bermuda, due to its great distance from the neighbouring continent, prevents its receiving much foreign detritus, and its submarine deposits are almost wholly local. The great bulk of these is calcareous, with some spicules of siliceous organisms. True coral sand is absent; indeed, there is a great rarity of coral fragments, for although corals flourish on the reefs, they do so in a subordinate manner. The Bermuda plateau is of interest in illustrating the growth of a limestone island where reef-building corals are of slight importance. The organisms chiefly active in the formation of the shell-sands are corallines, molluscs, tube-building worms, millepores, and foraminifera. Algæ probably form the greatest mass of the sand. White marls are described as due to the slow trituration of wind-borne material. There are also limited areas of blue mud. This seems to be of terrigenous origin, being the fine detritus washed down by rain from the calcareous hills, with vegetable matter.

To the March number of the *American Naturalist* Dr. A. Hollick contributes a paper on the occurrence and origin of amber in the eastern United States. Although amber has for many years been known to occur in several

districts in this part of America, a discovery of the occurrence of this substance in large masses has been recently made in the Cretaceous deposits of Kreischerville, Staten Island, N.Y. The amber, which is being extensively worked for commercial purposes, occurs in a bed containing layers and masses of vegetable débris, together with lignite and pyrite. The bed appears to be lens-shaped. Some at least of the amber is presumed to be the product of sequoias, but it is possible that a species of Pinus, and perhaps a representative of the Austro-Malayan genus Dammara, may have contributed to its production. The remaining articles include one by Prof. Hallow on the structure of the vascular cylinder in hybrid catalpa trees; a second, by Messrs. Cushman and Henderson, on fresh-water rhizopods from New Hampshire; and a third, by Dr. F. W. Carpenter, on the behaviour of a fruit fly under certain stimulants.

A DESCRIPTION of the large diamond found recently in the Premier Mine, Transvaal, is given in the *Geological Magazine* (April) by Dr. F. H. Hatch and Dr. G. S. Corstorphine, with reproductions of four photographs which represent the diamond in its actual size from four

FIG. 1.—View of the Cullinan Diamond. Actual size. From a photograph by E. H. V. Melvill.

different points of view. One of these pictures is here given (Fig. 1), and it conveys a good idea of the size and shape of the crystal. The stone is bounded by eight surfaces, four of which are faces of the original crystal, and four are cleavage surfaces, which are distinguished from the original octahedral faces by greater regularity and smoothness. For a large stone the crystal is of remarkable purity, and the colour approaches that of a blue-white. The complete crystal appears to have been a distorted octahedron, with dodecahedral faces developed on the edges; and the portions missing probably amount to more than half the original crystal. The stone, which has been named the Cullinan diamond, weighs 9600·5 grains troy, or 1·37 lb. avoirdupois; this is more than three times the weight of the largest diamond previously known.

SOME account of the Mount Morgan Gold Mine, Queensland, is given by Mr. E. J. Dunn (*Proc. Royal Soc. Victoria*, vol. xvii., part ii.). The hill, which rises to a height of 580 feet, is formed mainly of igneous rocks, within which are enclosed masses of decomposed rock, made up of siliceous and ferruginous material, and overlying these is a plug of Desert Sandstone, nearly 100 feet thick in places. The sandstone occupies a hollow in loose sandy beds overlying a ferruginous layer, and these beds yielded the rich secondary ore for which Mount Morgan has been celebrated. No naturally formed gold is known that more nearly reached chemical purity. At a much lower depth, in what is known as the sulphide zone, the gold is much alloyed with silver. The silver was got rid of in the transference of the leached ore to the enriched zone. The state of subdivision of the gold in this zone was so extreme that rich samples, in some cases those carrying 50 oz. per ton, showed no traces of gold that could be detected by the naked eye. The author attributes the formation of the secondary ore to the mechanical and chemical action of sea-water on the sulphide ore, there being evidence of considerable local erosion before the horizontal beds of Desert Sandstone were laid down.

THE Canadian Department of Marine and Fisheries has published the meteorological results obtained at the magnetical observatory at Toronto for the year 1904, with remarks, in a handy and useful form. The monthly means are in most cases compared with an average of sixty-four years, and are consequently of considerable value. The mean temperature of the year 1904 was 42°·2, being 2°·2 below the average. The maximum daily mean was 78°·9, on July 18, and the coldest day −8°·5, on January 14. The rainfall measured 30·04 inches (3·05 inches above the yearly average); this amount does not include 56·5 inches of snow, which is measured quite separately from rain.

AN important step for the promotion of New South Wales meteorology is recorded in the *U.S. Monthly Weather Review* (vol. xxxii., No. 11, p. 518). It seems that the principal newspaper of the colony, the *Daily Telegraph*, has commenced the publication of a daily weather chart. The origin of this step is stated in the following brief extract from the first number of the paper which contained this new information, a more complete account of which is inserted in the *Weather Review* referred to above:—"The inclusion of meteorology in the new public schools syllabus has directed special attention to consideration of weather conditions. Correspondents, including a number of public school teachers, have applied to the *Daily Telegraph* for amplified daily information on this subject, and the meteorological branch of the Sydney Observatory also has been requested to furnish details of the weather conditions and atmospheric pressures, the information upon which the weather forecasts are made. The *Daily Telegraph* has arranged to publish daily a chart showing the principal features of weather conditions, including the high and low pressure isobars. Where possible the rainfall area will be indicated and conditions on the coast will also be given. . . . The publication of isobaric charts will enable students with their local knowledge of physical surroundings to anticipate in detail their probable weather more completely than is possible at the central

office, where precise knowledge of local peculiarities is lacking." Those acquainted with Australian meteorology will appreciate the importance of disseminating a knowledge of this valuable factor in Australian welfare. In many countries the absence of public interest in the science of the weather is due to its omission from all school instruction, and we in Great Britain are suffering from the same neglect.

THE current number of the *Fortnightly Review* contains an article by Major B. Baden-Powell, president of the Aëronautical Society, entitled "Air-ships and M. Santos Dumont." Major Baden-Powell supplements and criticises a contribution by M. Santos Dumont to an earlier number of the same review on air-ships. He also points out some of the advantages to be gained by flying machines not dependent on a light gas to lift them, and directs attention to a few of the drawbacks inherent in the large gas-bag. The attainment of human flight, he contends, apparently presents no insuperable difficulties. "All that is wanted, so far as I can see, is a few thousand pounds and a clever and energetic inventor, and there is no reason why a machine could not be constructed within a year or two capable of rising and carrying a man in safety for, at all events, a short trip through the air."

THE water jet affords a most convenient method of applying the power carried by high-pressure water, whether for driving wheels, such as are generally known as Pelton wheels, for conveying the water itself into burning buildings, or for the destructive process of breaking down a mountain side, as practised in hydraulic mining. All this is especially the case in mountainous country where water supply with almost unlimited head is available. As it is not always necessary that the jet should work at full power, regulation becomes necessary. Merely reducing the flow of water by throttling elsewhere than at the jet would be ruinously wasteful, for half the flow would carry one-quarter the power, and a driven wheel would no longer run at the proper speed. The regulating nozzle described in a thesis entitled "An Investigation of the Doble Needle Regulating Nozzle," by H. C. Crowell and G. C. D. Lenth (printed by permission of the Civil Engineering Department of the Massachusetts Institute of Technology, Boston, and Tangential Water Wheels, Abner Doble Company), contains a spindle-shaped concentric needle which may be advanced so as to reduce the area of the orifice or withdrawn so as to enlarge it, but the form of the annular passage-way is always such as to lead the water to converge along easy stream lines, until a circular jet of corresponding size is the result. In this way a range of 10 to 1 in the area of the jet may be attained, while the full head is always available. Very beautiful photographs are given showing the jets like clear glass rods instead of the familiar opaque and spray-clothed stream of water. Efficiencies from 96·4 to 99·3 for the energy of the jet are found, which correspond to 98·2 to 99·7 for the velocity.

IN vol. vi. of the *Transactions of the American Electrochemical Society*, which has just been published, Messrs. A. G. Betts and E. F. Kern publish a paper on the "lead voltameter." Two years ago Mr. Betts found that lead could be deposited in a non-crystalline and dense form from solutions of lead fluosilicate to which had been added a small quantity of gelatin. The Canadian Smelting Company now manufactures more than twenty tons a day of refined lead from solutions of lead silicofluoride. Until Mr. Betts discovered this process it had not been found possible to refine lead electrolytically. By using the above solution the authors have constructed a voltameter which is—according to their published results—more accurate than the copper coulombmeter, and does not fall far behind the silver instrument. A glass beaker is used as the electrolysing cell, and a kathode of thin lead sheet is hung between two anodes of the same metal. The calculated value of the electro-equivalent of lead is 103·46. In this instrument, in which the electrolyte was 8·5 per cent. $PbSiF_6$, 2·5 per cent. H_2SiF_6, and a small quantity of gelatin, the numbers found in six experiments ranged from 103·39 to 103·49. Among other papers of interest in the same journal we note the electrolysis of fused salts, by Dr. Lorenz; the electrical extraction of nitrogen from the air, by Mr. J. S. Edström; electrolysis and catalysis, by Dr. W. Ostwald.

THE latest number of the *Journal of the Russian Physical and Chemical Society* (1904, No. 9) contains the conclusion of an interesting study, by B. N. Menshútkin, on Lomonósoff as a natural philosopher and a chemist. Lomonósoff's services in the creation of the Russian literary language and poetry are well known; but the remarkable work of this eighteenth century natural philosopher, of whom his friend and correspondent, Euler, always spoke with great respect, had hitherto found no proper appreciation in his mother country. His ideas upon the structure of matter, the atomistic theory of chemical changes, the mechanical theory of heat, his kinetic theory of gases, his views on the liquid and the solid state, and his theory of atmospheric electricity, which, he said, is always present in the atmosphere, and originates from the changes in the thermal potential of ascending and descending air currents—all these theories being based upon molecular movements within the bodies—were expressed in terms almost identical with those which are used now. "It is," he wrote, "the inner, unseen motions of the corpuscles of which all bodies are composed which are the cause of every rise of temperature in a given body. These movements are rotatory. When a cold body is brought into contact with a hot one, the latter communicates to the former the movements of its particles, which therefore are slackened in the hot body, and accelerated in the cold one. The greater these rotatory movements, the greater the repulsive forces, and the weaker the connection between them."

DR. A. C. HADDON, F.R.S., is delivering a course of lectures on Saturdays at the Horniman Museum, Forest Hill, S.E., on "Magic and Primitive Religion."

THE first volume, that for 1904, has been received of a series of yearly publications to be issued by the Chemical Society under the title "Annual Reports on the Progress of Chemistry." The object of these reports is to present an epitome of the principal definite steps in advance which have been accomplished in the preceding year. The first volume contains articles on general and physical chemistry, by Prof. James Walker, F.R.S.; on inorganic chemistry, by Dr. P. P. Bedson; on the aliphatic division of organic chemistry, by Mr. H. J. H. Fenton, F.R.S.; on the aromatic and other cyclic divisions of organic chemistry, by Prof. J. B. Cohen; on stereochemistry, by Prof. W. J. Pope, F.R.S.; on analytical chemistry, by Mr. A. C. Chapman; on physiological chemistry, by Prof. W. D. Halliburton, F.R.S.; on agricultural chemistry and vegetable physiology, by Dr. J. A. Voelcker; on mineralogical chemistry, by Dr. A. Hutchison; and on radio-activity, by Mr. F. Soddy. These summaries of the chief advances in various branches of chemical science should prove of real benefit to students, teachers of chemistry, and professional chemists.

OUR ASTRONOMICAL COLUMN.

EPHEMERIS FOR COMET 1905 *a*.—A set of elements and a daily ephemeris for comet 1905 *a* are given in No. 4011 of the *Astronomische Nachrichten*. The ephemeris has been computed by Herr M. Ebell, and an extract is given below:—

Ephemeris 12h. (M.T. Berlin).

1905	α (true) h. m. s.	δ (true) ° ′	log r	log Δ	Brightness
May 12	9 45 27	+49 15·8	0·1066	9·9814	0·42
16	10 8 56	+49 44·2	0·1172	0·0002	0·36
20	10 31 29	+49 51·5	0·1281	0·0189	0·32
24	10 52 58	+49 40·1	0·1394	0·0375	0·28
28	11 13 11	+49 13·1	0·1508	0·0558	0·24
June 1	11 32 9	+48 32·8	0·1623	0·0740	0·21
5	11 49 51	+47 41·8	0·1739	0·0919	0·18

COMETS 1905 II (1904 *e*) AND 1904 I.—A daily ephemeris for comet 1904 *e*, computed by Dr Strömgren, is given in No. 4011 of the *Astronomische Nachrichten*. The comet is now very faint, and as seen by Dr. Palisa at the beginning of April it was 10″ in diameter, and had a fourteenth-magnitude nucleus. During the present month it will apparently travel through the constellation Lynx in a south-easterly direction towards Leo Minor.

A bi-daily ephemeris for comet 1904 I, computed by Herren Nijland and van d Bilt, is given in the same journal. This comet is also faint, being 0·052 as bright as when first discovered, its magnitude then being about 9·0. It is likewise situated in the constellation Lynx, and is apparently travelling in a S.S.E. direction towards Cancer, although at the beginning of September it will only be about 3° south of 35 Lyncis.

OBSERVATIONS OF JUPITER.—The results of their observations of Jupiter during the 1904–5 opposition are given by MM. Flammarion and Benoit in the May number of the *Bulletin de la Société astronomique de France*. Numerous points of change in the colours and forms of the various features are noted, and some of them are illustrated on the four drawings accompanying the article. Among the other conclusions derived from these observations the writers state the following:—(1) the estimations of the coloration of the equatorial bands do not confirm Mr. Stanley Williams's views as to periodical changes therein; (2) the appearance of the Great Red Spot has not changed since the previous opposition; (3) the large variation of the longitude of this feature between March and June, 1904, was probably due to the passage alongside it of the dark region of the tropical zone; (4) a clear spot situated in longitude 0° of system ii., and dividing the south equatorial band, appears to be a permanent feature which it will be well to observe assiduously. They further urge that careful attention should be paid at the end of this year to observations of the movements of the red spot, of the bright spots on the southern edge of south temperate band announced by Mr. Denning, and of the dark region situated in the south tropical zone.

THE ELECTRIC CHARGE OF THE SUN.—In No. 1, vol. x., of *Terrestrial Magnetism and Atmospheric Electricity* is reprinted the address "On the Electric Charge of the Sun" delivered by Prof. Svante Arrhenius before the International Electrical Congress held at St. Louis last September.

After briefly discussing the various theories regarding the nature of the sun's repulsive action, the author shows that the theory which explains the phenomena, by premising that the repulsion is due to radiation pressure acting on negatively charged particles, is in accordance with observational records. The particles having a specific weight of 1·0 and a radius of 0·08 μ are those which are repelled at the greatest speed, and would reach our atmosphere in about 45·9 hours, an interval of the same order as that obtained by Riccò for the time intervening between the probably correlated solar and terrestrial phenomena. These particles are negatively charged in accordance with Mr. C. T. R. Wilson's proof that such particles are more easily condensed on negative than on positive ions, the ionisation of the solar atmosphere resulting, as Lenard has shown, from the action of the sun's strong ultra-violet radiation. By a simple calculation Prof. Arrhenius shows that the remaining positive charge is balanced, and the balance maintained, by the attraction of negative electrons emitted by other celestial bodies which are negatively charged and lose their charge under the influence of their ultra-violet rays. All such rays coming within a mean distance of 0·063 light-years of the sun will be attracted thereto, and by this means the supply of negative electrons becomes just proportional to the defect thereof.

VARIABILITY OF MINOR PLANET (15), EUNOMIA.—*Circular* No. 94 of the Harvard College Observatory is devoted to an account of Prof. Wendell's observations of the minor planet Eunomia, from which he established a variation of magnitude of about 0·5. The observations were made with a photometer having achromatic prisms and attached to the 15-inch telescope. As the planet was near its stationary point it was compared with the same star, +13° 1875 (mag. 9·0), from March 15 to April 1, and the corrected differences varied from −0·77 to −1·11. The formula J.D. 2416920·116+0·1267 E. expresses the phase and period of the changes. The period is very similar to that found for minor planet (7), Iris, viz. 0·1295d., and in both cases it is still doubtful as to whether the period requires doubling or not.

FAINTNESS OF PLANETARY NEBULÆ.—Some interesting results of calculations appertaining to the luminosity of the surfaces of several planetary nebulæ, as compared with the surface luminosity of the sun or the moon, are given in a letter written by Mr. J. E. Gore to the current number of the *Observatory*.

Dealing with the nebula H, iv. 37, situated near to the pole of the ecliptic, he finds that the ratio of its surface luminosity is to that of the sun's as $1 : 43196{\cdot}7 \times 10^6$. The similar ratios for the nebulæ h 3365, Σ 5, and G.C. 7027 are $1 : 245{\cdot}3 \times 10^6$, $1 : 1095{\cdot}5 \times 10^6$, and $1 : 434 \times 10^6$ respectively; thus the brightest of them, *i.e.* h 3365, has a surface luminosity of only 1/400 that of the moon.

THE COWTHORPE OAK.

IN the *Transactions and Proceedings of the Botanical Society of Edinburgh* (vol. xxii., part iii., 1904, p. 396) we notice a very interesting article on the Cowthorpe Oak from the pen of Mr. John Clayton. This venerable tree, which stands near the church of Cowthorpe, a small village near Wetherby, is unique among oaks in that its girth is greater than that of any other known tree of its species. Recorded measurements taken about 1700 show that it had at that time a height of 80 feet with a girth of 78 feet on the ground. Since then various observers have recorded its dimensions and noted at the same time the gradual process of decay, damage by storm, and other points likely to be of interest. The latest measurements were taken by Mr. Clayton himself, and they show that the height is now reduced to 37 feet including dead wood, while the girth on the ground has diminished to 54 feet 3 inches. In 1893 a crop of acorns was produced, from one of which a seedling was reared, and is now planted near its parent as a memorial.

The tree stands in a warm, sheltered spot in a field which has a gentle slope to the river, and near enough to get a constant supply of water. The process of decay has been going on for the last 200 years. Between 1703 and 1722 much damage was done by various storms; nevertheless, new leaves are put forth annually. The acorns produced in 1893 were on long stalks—hence the species is *Quercus pedunculata*. As regards the age of this giant opinion seems to differ. The trunk, being now hollow, precludes all possibility of ever ascertaining the number of year-rings, and no trustworthy data are available before the year 1700—hence the author has been compelled to rely upon a comparison with the age of other trees. In a tree the duration of life may be taken as composed of

three periods, one of growth, one of maturity, and lastly one of decline and decay. Between the number of years in each period a certain ratio is found to exist, and, taking this as a basis, together with what is known of the tree since 1700, Mr. Clayton arrives at the conclusion that its age is not more than 500 years—certainly much nearer the mark than the age of 1600 years assigned to it by Prof. Burnett in 1842, who based his calculation on the theory of the elder De Candolle that a tree increases by one-twelfth of an inch in diameter annually, an altogether untrustworthy basis of calculation.

There is quite a number of other interesting historical trees dealt with in the article, for example, the Greendale Oak in Welbeck Park, which belongs to the Duke of Portland. Its height was recorded by John Evelyn in 1846 as 88 feet, while the altitude of the highest twig at the present day is only 54 feet. In 1724 a roadway was cut through the trunk, which girths 30 feet 1 inch at 4½ feet from the ground. The height of the archway was then 10 feet 2 inches, but recent measurements show that the highest point is now only 9 feet 3 inches, and the lowest 8 feet 6 inches. This shows conclusively that a subsidence of the trunk must have taken place within the last 200 years, and, by assuming that a similar sinking into the ground has occurred in the case of the Cowthorpe Oak, Mr. Clayton explains the apparent discrepancies between the earliest and latest recorded girth dimensions of the veteran. The trunk being somewhat tapering, the diameter naturally lessens as the sinking in proceeds. Mr. Clayton adds a note on the testimony of a Cowthorpe man named Oates, who said, "The tree has shrunk very much in my time, and in shrinking the tree has twisted—the Eastern branches towards the South."

Another notable tree as regards size and age is the Crowhurst Yew, which girths 34 feet 4 inches on the ground. It stands in the churchyard of that place. The church must be very old, as it contains monuments of Saxon and Norman workmanship. The author points out that the oldest trees are usually in close proximity to a sacred edifice, such as this yew and the Cowthorpe Oak, and the association no doubt affords them protection.

Another notable veteran is the great chestnut of Tortworth, Gloucester, which girths 49 feet 2 inches at 4 feet from the ground. It also stands about 100 yards from a very old and beautiful church.

As regards the longevity of trees, the theory was promulgated at the beginning of the nineteenth century by De Candolle that the duration of life in trees was practically unlimited, neglecting accidents due to unfavourable external conditions, such as the ravages of parasites, injuries from storms, lightning, and other causes. Passing in review the vegetable kingdom, we find there are some lowly organised plants, such as certain algæ and fungi, the whole life cycle of which may be completed within the short space of a few days, or even hours. Among the higher plants we have annuals and biennials the existence of which terminates with the production of seed. Then we have the agave and certain palms, the aërial portions of which may live from ten to forty years until the production of flower and fruit terminates their span of life, their place being taken by new aërial portions developed from lateral buds at the base of the plant. In the case of trees and woody shrubs, on the other hand, new growing points are formed annually, but this vegetative process does not end in the production of flower and fruit, so that, excluding accidents, there is no reason why that vegetative process should not be continued for an unlimited time.

Cowthorpe Oak, seen from North. The tree is supported by twenty-five props, disposed mostly on the South and East sides. There is a paling about 5 ft. high, which seems as if it had been put up from twenty to forty years ago.

The giant Wellingtonias of California are well known examples of the age and dimensions which trees may attain. A stem in the British Museum shows 1330 year-rings with a diameter of about 15 feet. On the other hand, certain Japanese dwarf trees are known to be of very great antiquity, although lacking the size of the Wellingtonias. At the same time, one must not lose sight of the fact that the living cells are continually being renewed, and that in a tree like the Cowthorpe Oak the living parts are at most but a few years old.

FISHERY INVESTIGATIONS IN THE NORWEGIAN FJORDS.[1]

DR. NORDGAARD has collected the results of investigations made in some of the fjords of northern Norway in the winters of 1899 and 1900, during the course of researches in the fishing waters of Lofoten, carried out at the expense of the Bergen Museum and the Norwegian Government. Two "expeditions" were made. The first, January to May, 1899, included the Vest Fjord and the sea beyond Lofoten, Vesteraalen, Sengen, and Finmarken, besides a large number of fjords, as the Kirk, the Øgs, the Kanstad, the Sag, and many others. The second, in the winter of 1900, was made so as to obtain material from the fishing banks which would compare with that of the previous year, and it included visits to the Morsdal, Salten, Skjerstad, and Folden fjords.

The hydrographical observations, which are numerous, have been made according to recognised standard methods, and are therefore comparable with observations made further out at sea, in the regions in which the full explanation of many of the facts brought to light here is doubtless to be found. The chief hydrographical result arrived at by Dr. Nordgaard is that the northern fjords can be divided into two groups, those in which the bottom temperature is 6° C. to 7° C., and salinity about 35 *pro mille*, and those in which the bottom temperature is below 6° C., and salinity less than 35 *pro mille*. As examples of the former, the Salten, Folden, Tys, Ofot, and Vest fjords are given, and as examples of the latter the Malang, Lyngen, Kvaenang, Porsanger, Tana, Varaanger, Skjerstad, Skjomen, Kanstad, Øgs, and Kirk fjords. It is suggested that while in some cases, as the Skjerstad fjord, the inflow of ocean water is cut off by a submarine ridge, the occurrence of the two typical groups may be accounted for by the distribution of rainfall. The heavy winter rainfall in western Norway affords a large supply of fresh water to the surface layers of the fjords, which accordingly remain specifically light, notwithstanding the fall of temperature. In northern Norway the rainfall is much less, hence the surface waters retain a high salinity, and as their temperature falls they sink to considerable depths.

Dr. Nordgaard also discusses at some length the varying influence of different amounts of rainfall on the currents within the fjords. Heavy rainfalls, which raise the surface level of the water, are for the most part the result of winds from the ocean, which produce a similar effect; it is difficult to separate the effects of the two causes, but a rainfall above the average is taken as a fairly certain index of abnormal strength in the oceanic streams.

In the "biological notes" which accompany the tables a number of points are brought out showing and defining the connection between fauna and hydrography. It is shown that whereas in the first or warm-water group of fjords the deep-water fauna is chiefly boreal, in the second group, where cold water of lower salinity makes its way downwards, the predominant forms are Arctic. The effect of the increased precision of modern methods of investigation in greatly reducing the number of so-called cosmopolitan species is also emphasised.

The section of this memoir which deals with fisheries is specially important and suggestive. In discussing the Lofoten fisheries, Dr. Nordgaard adopts the view that the currents in the Norwegian Sea are controlled by the winds, and that, as already explained, abnormal movements of the currents off-shore or on-shore can be associated with rainfall above or below the average. Again, he says, "It is clear that during the movements to or from the coast of the surface water, a compensating current must be set in motion in the deep water; it has long been a recognised phenomenon in the fjords, that the surface and under currents go in contrary directions." From an examination of the observations, Dr. Nordgaard concludes that herrings move coastwards specially in the surface layers, while the cod travels along in the deeper layers. It must therefore, he continues, "be supposed that as cod and herrings, to a certain extent, depend upon contrary current phases, a particularly good spring herring fishery would prevent a correspondingly good cod fishery in the same district; for a strong tendency of the upper layers towards the coast certainly takes herrings along in the current, but this at the same time causes a compensation current in the deep water, and this current hinders the cod in its passage to the spawning places."

The statistics of the yield of the cod and herring fisheries for some years are discussed and compared with corresponding values of rainfall, with results which appear to support the hypothesis brought forward. It would of course be easy to suggest difficulties, such as the extension of the current *régime* observed in fjords to areas which can hardly be regarded as such, and may therefore have a different system of movements. But as the whole question is at present under investigation on the large scale by the International Council, we content ourselves with an attempt to summarise Dr. Nordgaard's results, deferring fuller discussion of them until the more abundant data are available.

[1] Bergens Museum. "Hydrographical and Biological Investigations in Norwegian Fjords." By O. Nordgaard. "The Protist Plankton and the Diatoms in Bottom Samples." By E. Jørgensen. Pp 254; with 21 plates and 10 figures in the text. (Bergen: John Grieg, 1905.)

A NEW SLIDE RULE.

MESSRS. JOHN DAVIS AND SON, of Derby, the well known instrument makers, are bringing out a variation of the slide rule which is likely to increase its value for certain classes of calculation without interfering with the simplicity and convenience of the form with which we are all familiar. The lower groove on the outside of the rule, which ordinarily is only wide enough to hold the inturned edge of the cursor, is made wider, so as to take one of the tongues of a spare slide, and this slide is held in place when required by two light aluminium clips which grasp the ends of the rule and of the spare slide while leaving the usual slide free to move. An extra cursor is also provided which is long enough to grasp both the rule and the extra slide. By this means any rare or special scales upon the extra slide are for the time being equivalent to scales upon the rule, and these may be read against scales upon the other slide by means of the long cursor. If desired, the extra slide can take the place of the ordinary slide, or may be removed altogether when the rule, if provided with an ordinary cursor adapted to the altered lower groove, becomes an ordinary slide rule. In the example submitted, the extra slide carries what are called E and −E scales. The E scale is a log log scale, and is always being re-invented; it was called a P line or power line by Lieut. Thomson, who showed it at the Inventions Exhibition, and it was long before invented by Dr. Roget. This P or E line is very handy, for it at once enables the logarithm of any number on any scale, *i.e.* to any base, to be read according to its position against an ordinary A line, while fractional or high powers of numbers are read with equal facility. Compound interest, pressures and volumes of gases under isothermal or adiabatic conditions are readily evaluated with the aid of the E line read against an A line. If, however, a pair of E slides are used, one in the usual position and one attached below the rule by means of the clips, then against any value, say of v, on one, the cursor will show the value of v^γ on the other, γ having any desired value according to the relative position of the two slides.

The slide rules made by Messrs. Davis and Son are too well known for their accuracy and finish for it to be necessary to refer more to such points, but by some curious perversity or accident there is one little fault in the rule sent for examination which only needs to be pointed out to be put right. On the feather edge a scale of inches in 16ths is provided; on the lower face outside the rule there is no scale at all, while inside, to be used like a hat measure, there is a scale of millimetres beginning at 550. If, therefore, the rule is required for the prosaic but very useful purpose of measuring a length, this can only be measured in inches if it is 20 inches or less, or in millimetres if it lies between 550 and 1040 millimetres. If,

therefore, the bald outside edge were divided in millimetres, the whole range would be available for metric measurement, and if the lower half of the space at the back of the slide now empty were divided in inches, hat measurements from 20 to 41 inches would complete the range for the English scale. C. V. B.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—Mr. Frederick Wilkin, of Lower Consley Wood, Wadhurst, Sussex, proposes to found a studentship in memory of his son, Mr. Anthony Wilkin, late of King's College, and for this purpose he proposes to make over to the university the tithe rent charge on Wadhurst Parish. This benefaction is for the furtherance of ethnological and archæological research, and the holder is to be termed "The Anthony Wilkin Student." It is proposed that the student shall be selected by the board of anthropological studies; the income is estimated at about 40*l*. a year, and the board suggests that this should be accumulated for periods of five years in order that a substantial sum of about 200*l*. may be available for the selected candidate. The first studentship will be offered in 1910.

Mr. W. W. Watts, of Sidney Sussex College, Mr. H. Y. Oldham, of King's College, Mr. A. R. Hinks, of Trinity College, and Mr. G. G. Chisholm have been appointed examiners for part ii. of the examination for the diploma in geography.

A combined examination of non-resident candidates for open scholarships, exhibitions, &c., will be held at Trinity College, Clare College, Trinity Hall, Peterhouse, and Sidney Sussex College, Cambridge, beginning on Tuesday, December 5. Forms of application for admission to the examination may be obtained from any of the tutors of Trinity College, the senior tutor of Clare College, the tutor of Trinity Hall, the senior tutor of Peterhouse, or the master of Sidney Sussex College, to one of whom the form of application (when filled up), together with certificates of birth and of moral character, should be sent. Entries should be made not later than November 23.

A teaching observatory will, it is reported by *Science*, be established by the Ontario Government at the University of Toronto. Dr. C. A. Chant expects to visit the observatories of the United States to study their plans and methods.

A conference of scientific students was held at Colorado College, Colorado Springs, on April 28 and 29, and representatives of leading universities and colleges were present. A number of papers upon subjects relating to the scientific problems of the Rocky Mountain country were read. A similar conference, held a year ago at the same institution, was of such importance that it led to this second series of meetings.

With the view of making the municipal museum a centre of education in the broad principles of natural science, the Hull authorities have arranged with the curator, Mr. T. Sheppard, for the delivery by him of simple lectures to school children on geology, zoology, and anthropology. The lectures are given in the mornings by arrangement. Permission for pupils to visit the museum must be obtained from the clerk of the education committee. Each lecture lasts about half an hour, and is illustrated by objects from the cases. The remainder of the morning is occupied in examining the specimens, taking notes, and making sketches.

Mr. A. C. Benson contributes to the *National Review* an important article on an Eton education. Mr. Benson, though a classicist, is by no means satisfied with the existing state of educational matters at Eton. Describing the average boy who leaves Eton, Mr. Benson says:—"The basis of his education has been, as a rule, the classical basis; that is to say, the greater part of his working hours have been devoted to Latin and Greek. A small percentage of fair classical scholars and a still smaller sprinkling of distinguished classicists is the result. But the average boy leaves Eton with no mastery of either of these languages. He cannot, as a rule, construe at sight an easy passage in either, or turn a piece of English into either language without a large crop of mistakes." In another place Mr. Benson states that the boy "never reaches the stage at which classics become literature." He urges that for the large class of boys who are not intended for the university, the strictly classical programme might be with advantage modified. Mr. Benson believes that a boy who left school with a thorough knowledge of French, "who knew the elements of science, so as to be able to understand something of what was going on in the world around him, in heaven and earth and sea, in field and wood," who knew arithmetic and had a reasonable knowledge of geography and history, would leave school a fairly educated man. Mr. Benson would have a very simple core of education on the lines just indicated, and then any evidence of special capacity, linguistic, mathematical, scientific, or historical, should be carefully observed, and at a certain age a boy's studies should converge more closely upon a special subject, care being taken at the same time that the general education should not be neglected.

A valuable address was delivered by Prof. A. Pedler, F.R.S., Vice-chancellor of the University of Calcutta, and Director of Public Instruction with the Government of Bengal, at the recent convocation of the Senate of the university for conferring degrees. During the course of his remarks, Prof. Pedler said that fifty years ago university education in Bengal had no existence, the doors of western learning had not been opened, and the knowledge of western science was absolutely beyond the reach of anyone in the country. During the last half-century the possibilities of obtaining western knowledge and western culture, and the facilities for higher education, have been rapidly developed, until a whole network of educational institutions has been spread over Bengal. Inquiring as to whether the form of education being given to the people is affecting them in the most satisfactory way, Prof. Pedler came to the conclusion that it is not. The arrangements, he said, are wanting in concentration of effort, in thoroughness of method, and in the intelligent appreciation of means to ends. After instituting a comparison between what has been accomplished in Japan and in Bengal, he came to the conclusion that the secret of the brilliant success of university education in Japan is to be found in the observance of certain cardinal principles, viz. patience in obtaining results; thoroughness in work; concentration of university work in a few really well equipped and strongly staffed colleges, each institution being devoted to a special section of learning, which is taught thoroughly; adaptation of the courses to the practical wants of life and of modern civilisation, as exemplified by the large proportion of graduates who elect the practical rather than literary courses of study; originality as shown by the large number of young men who undertake research work, and also shown by the large number of original contributions in science. In the future, Prof. Pedler remarked, it will be necessary in Bengal to adopt all these principles and to adhere to them with uncompromising tenacity, if university work is to be placed on a really satisfactory footing. The principles could also be applied with profit to a large part of the work of our own educational institutions.

SOCIETIES AND ACADEMIES.

London.

Geological Society, April 19.—Mr. H. B. Woodward, F.R.S., vice-president, in the chair.—The Blea Wyke beds and the Dogger in north-east Yorkshire: R. H. **Rastall.** The author describes the type-section at Blea Wyke in detail, dividing the rocks into the following divisions, enumerated in descending order:—(5) Dogger; (4) yellow beds; (3) Serpula beds; (2) Lingula beds; (1) Striatulus shales. Descriptions and fossil lists from these divisions are given, and the succession is compared with others.—Notes on the geological aspect of some of the north-eastern territories of the Congo Free State: G. F. J. **Preumont,** with petrological notes by J. A. **Howe.** This paper is a brief sketch of the geological structure of the northern part of the Congo State, from Buta on the River Rubi and Bima

on the Uelle in the west, to Lado and Dufile on the Nile. In the whole of this region, the only post-Primary rocks met with, other than those of comparatively modern alluvial origin, were chocolate-coloured shales (Buta Shales) and sandstone, and an Oolitic limestone, on the extreme west. From the Lipodongu Falls on the Rubi, and thence through Poko to Rungu, on the Bomokandi River, none but granitic rocks (gneisses) were observed. Along the Uelle, from Bima to Bomokandi, the same rocks were seen. In the centre of the region mica-schists, quartzites, and similar metamorphic rocks replace the granite wholly or in part. A noticeable feature here is the presence of a range of isolated hills, composed almost completely of great beds of magnetite and hæmatite occurring in the schistose series. In the south-eastern portion of the region visited, between the Uelle-Kimbali and Bomokandi rivers, a great plutonic massif is laid bare in the mountainous district of Arebi. The plutonic massif itself contains microclinic gneiss, and abundant diabasic rocks, and the same rocks in all stages of dynamo-metamorphism. On the boundary between the Congo State and the Bahr-el-Ghazal, several hills made up of rocks of coarse gneissose and schistose character are described; some of these rocks are rich in tourmaline, kyanite, and garnet in large crystals. From the region of the Enclave de Lado and the western side of the Nile between Lado and Dufile, mica-schists, quartzites, and microcline-gneisses are described. The alluvium of a large part of the Uelle is covered, on the higher ground, by a deposit of limonitic conglomerate; in places this may be due to the decomposition *in situ* of the alluvium, but in the neighbourhood of the iron-mountains a sort of passage may be seen between a conglomerate of fresh iron-ores and the more general type of limonitic conglomerate (laterite?).

Paris.

Academy of Sciences, May 1.—M. Troost in the chair.—New researches on chemical combination: M. **Berthelot**. Various substances were sealed up in fused quartz tubes, heated for one hour at 1300° C. in an electric furnace, and suddenly cooled by dropping into water. Nitrogen and hydrogen gave no trace of ammonia; ammonia was completely split up into its constituents, and the stability was not increased by the presence of hydrochloric acid. The latter gas, heated alone, was not decomposed, and hydrogen sulphide behaved similarly if the cooling was slow, but showed evidence of dissociation into hydrogen and sulphur with instantaneous cooling.—On the permeability of tubes of fused silica: M. **Berthelot**. At the ordinary temperature, no hydrogen will pass through the walls of a fused quartz tube, even into a barometric vacuum, and even at 600° to 800° no appreciable amount passes through. At 1300° C., on the other hand, the amount transpired is considerable. Neither hydrochloric acid nor carbon dioxide get through at 1300° C.; the transpiration of nitrogen is not sensible at 600° C., very slight at 1000° C., becoming marked at 1300° C. to 1400° C. Some preliminary experiments with glass at lower temperatures appear to show similar effects, and these observations are being continued.—The action of mercuric iodide on sulphuric acid and on the sulphates of mercury: Alfred **Ditte**.—On the earthquake of April 29: M. **Mascart**. The seismograph at Bagnères-de-Bigorre showed horizontal vibrations at 2h. 1m. 20s., whilst the same oscillation was indicated at Grenoble at 1h. 59m. 15s., a difference of time corresponding to the rate of transmission through the ground.—On the triboluminescence of arsenious acid: M. **Guinchant**. The light given off by arsenious acid is due to the breaking and transformation of the crystals after their formation. The radiations are actinic, and are without any effect on the electroscope. Similar phenomena taking place during the reduction of hypochlorites and hypobromites are described, the effects in this case being attributed to the production and decomposition of haloid compounds of nitrogen.—On the physical impossibility of putting in evidence the motion of translation of the earth: P. **Langevin**. In a discussion of an experiment by Trouton and Noble it is proved that it ought to give a negative result for all orders of approximation and whatever system of suspension be employed for the condenser.—On the heat of vaporisation of liquefied gases: E. **Mathias**.—Heat in the displacement of a capillary system: M. **Ponsot**.—On the difference in temperature of bodies in contact: E. **Rogovski**. Fine wires of different diameters were heated by an electric current, and cooled by water flowing at known rates. The temperature of the wire was measured by means of its electrical resistance, and the difference of temperature between the wire and the cooling water determined as a function of the rate of flow of the water and of the diameter of the wire.—The preparation of anhydrous chlorides of the metals of the rare earths: Camille **Matignon**. The solid material obtained by the evaporation of the solution of the oxide in hydrochloric acid is heated in a current of chlorine and hydrochloric acid gas charged with the vapours of chloride of sulphur. It is possible to obtain in this way very rapidly either large or small quantities of anhydrous chlorides. Particulars are given with analyses showing the purity of the products, of the chlorides of lanthanum, neodidymium, praseodidymium, samarium, and yttrium.—On cæsium amide: E. **Rengade**. The amide is prepared by the action of dry ammonia upon the fused metal at 120° C., the purity of the product being fixed by the determination of the amount of hydrogen evolved. The amide dissolves readily in liquid ammonia, and the solution absorbs oxygen at −60° C. giving a precipitate, the hydroxide and nitrite of cæsium being formed, together with ammonia.—On a new reagent for potassium: Eugenio Pinerua **Alvarez**. The reagent proposed is a 5 per cent. solution of sodium amido-naphthol sulphonate.—On the conditions of development of the mycelium of Morchella: G. **Fron**. The mycelium of this edible mushroom requires for its strong growth plenty of hydrocarbon food, inulin and starch being especially favourable; the mineral food is of less importance.—Calcium nitrate in agriculture: E. S. **Bellenoux**. The author proposes to replace nitrate of soda by the nitrate of calcium, and gives results of comparative trials of the two showing the superiority of the latter as a manure.—The variation of the osmotic pressure in muscle caused by contraction: Stéphane **Leduc**. It is shown experimentally that an elevation of the osmotic pressure in a muscle is a consequence of contraction, the rise of the pressure being more marked as the stimulations are more prolonged.—The variations undergone by glucose, glycogen, fat, and soluble albumens in the course of the metamorphoses in the silkworm: C. **Vaney** and F. **Maignon**.—On a combination of methæmoglobin containing fluorine: H. **Ville** and E. **Derrien**. In a previous paper the authors have shown that the addition of fluorine compounds to a solution of methæmoglobin causes a marked change in the absorption spectrum, and they were thus led to the conclusion that a definite compound might possibly be produced. This compound has been isolated in the crystalline form, details of its preparation and properties being given in the present note.—Philocatalase and anticatalase in animal tissues: F. **Battelli** and Mlle. L. **Stern**.—On the action of formic acid in nervous diseases accompanied with trembling: E. **Clément**. The use of formic acid has been attended with great success in certain cases.—The volcanic regions traversed by the Sahara expedition: F. **Foureau** and Louis **Gentil**.

New South Wales.

Linnean Society, March 29.—Mr. T. Steel, president, in the chair.—The botany of north-western New South Wales: F. **Turner**. The characteristics of the indigenous vegetation and the exotic weeds of the country lying between the New South Wales-Queensland border and 33° S. lat., and 147° and 151° 20′ E. long., are discussed. The census of the phanerogams and vascular cryptogams given comprises a total of 452 genera and 1137 species.—Contribution to our knowledge of the physiology of the pancreas: H. G. **Chapman**. The conclusions arrived at in this paper, which is a preliminary communication, may be summarised as follows:—(1) secretins from the echidna, wallaby, Australian water-tortoise, and ibis are active upon the dog in causing a flow of pancreatic juice; (2) secretin does not appear to cause pancreatic secretion in the echidna; (3) the flow of pancreatic juice produced by pilocarpine is inhibited by atropine, while the flow produced by secretin is not so

inhibited; (4) stimulation of the vagus nerve does not inhibit the secretion due to secretin; (5) the pressure under which the fluid is secreted in the pancreatic duct is equivalent to 9 inches of the juice; (6) pancreatic juice may be activated by leucocytes so that it acts upon proteids.

DIARY OF SOCIETIES.

THURSDAY, MAY 11.

ROYAL SOCIETY, at 4, Election of Fellows.—At 4.30, On the Resemblances existing between the "Plimmer's Bodies" of Malignant Growths and certain Normal Constituents of Reproductive Cells of Animals: Prof. J. B. Farmer, F.R.S., J. E. S. Moore, and C. E. Walker.—The Effect of Plant Growth and of Manures upon the Soil: the retention of Bases by the Soil: A. D. Hall and Dr. N. H. J. Miller.—A Study of the Process of Nitrification with Reference to the Purification of Sewage: Miss H. Chick.—Pathological Report on the Histology of Sleeping Sickness and Trypanosomiasis; with a Comparison of the Changes found in Animals infected with *T. gambiense* and other Trypanosomata: Dr. A. Breinl.—(1) The Experimental Treatment of Trypanosomiasis in Animals; (2) Remarks on Mr. Plimmer's Note on the Effects produced in Rats by the Trypanosomata of Gambian Fever and Sleeping Sickness: Dr. H. Wolferstan Thomas.

ROYAL INSTITUTION, at 5.—Flame: Sir James Dewar, F.R.S.

SOCIETY OF ARTS, at 4.30.—The Manufactures of Greater Britain. III. India: H. J. Tozer.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Telephone Traffic: H. L. Webb.

SOCIOLOGICAL SOCIETY, at 8.15.—Some Guiding Principles in the Philosophy of History: Dr. J. H. Bridges.

MATHEMATICAL SOCIETY, at 5.30.—On the Intersections of two Conic Sections: J. A. H. Johnston.—On a System of Conics yielding Operators which Annihilate a Cubic and its Bearing on the Reduction of the Cubic to the Sum of four Cubes: H. G. Dawson.—High Pellian Factorisations: Lt.-Col. A. Cunningham.

FRIDAY, MAY 12.

ROYAL INSTITUTION, at 9.—The Pressure due to Radiation: Prof. E. F. Nichols.

PHYSICAL SOCIETY, at 8.—A Simple Method of Determining the Radiation Constant; suitable for a Laboratory Experiment: Dr. A. D. Denning.—A Bolometer for the Absolute Measurement of Radiation: Prof. H. L. Callendar, F.R.S.—The Resistance of a Conductor the Measure of the Current flowing through it: W. A. Price.

MALACOLOGICAL SOCIETY, at 8.—Note on *Helix pellita*, Fér., and other Shells from the Pleistocene Cave-deposits of East Crete: Rev. R. Ashington Bullen.—Notes on Recent Spanish Shells from Granada and Carmona: Rev. R. Ashington Bullen.—Description of a new Species of Vitrea from Greece: E. A. Smith.—Descriptions of new Forms of Marginellidæ and Pleurotomidæ: E. R. Sykes.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Discussion of the Observations of the Satellite of Neptune made at the Royal Observatory, Greenwich, in the years 1902–3–4: F. W. Dyson and D. J. R. Edney.—Further Note on the Density and Prolateness of Close Binary Stars: A. W. Roberts.—On Hansen's Coefficients for the Inequalities in the Moon's Longitude: E. Nevill.—A Supposed Instance of Sudden Change on Jupiter: Major P. B. Molesworth.—Optical Distortion of the Object Glass of the Astrographic Telescope, deduced from Measures of the Eros Photographs, Communicated by the Astronomer Royal: Royal Observatory, Greenwich.—*Promised Papers*: On the Formula for Connecting Photographic Diameters with Stellar Magnitudes: H. H. Turner.—The Determination of Stellar Proper Motions without Reference to Meridian Observations: A. R. Hinks.—Notes on the Use of Thorp Gratings for Eclipse Work: Dr. W. J. S. Lockyer.

SATURDAY, MAY 13.

ROYAL INSTITUTION, at 3.—Moulds and Mouldiness: Prof. Marshall Ward, F.R.S.

MONDAY, MAY 15.

SOCIETY OF ARTS, at 8.—The Uses of Electricity in Mines: H. W. Ravenshaw.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Exploration and Survey in Central Tibet and to the Sources of the Brahmaputra: Captain C. H. D. Ryder.

VICTORIA INSTITUTE, at 4.30.—The Messiah of Quadian: The Rev. Dr. Griswold.

TUESDAY, MAY 16.

ROYAL INSTITUTION, at 5.—The Study of Extinct Animals: Prof. L. C. Miall, F.R.S.

ROYAL STATISTICAL SOCIETY, at 5.

ZOOLOGICAL SOCIETY, at 8.30.—A Contribution to the Knowledge of the Encephalic Arterial System in Sauropsida: F. E. Beddard.—On Stridulating Halyinæ with Descriptions of New Genera and Species: Dr. E. Bergroth.—On the Classification of the Anthropoid Apes as Proposed by the Hon. Walter Rothschild: Sir Harry Johnston.

SOCIETY OF ARTS, at 8.—Excavation of the Oldest Temple at Thebes: H. R. Hall.

WEDNESDAY, MAY 17.

SOCIETY OF ARTS, at 8.—The Use of Wood Pulp for Paper Making: S. Charles Phillips.

ROYAL MICROSCOPICAL SOCIETY, at 8.—The Movements of Diatoms and other Microscopic Plants: D. D. Jackson.—Exhibition of Slides of the Oribatidæ.

ROYAL METEOROLOGICAL SOCIETY, at 4.30.—Measurement of Evaporation: R. Strachan.—Logarithmic Slide-Rule for reducing Readings of the Barometer to Sea-level: Dr. J. Ball.

CHEMICAL SOCIETY, at 5.30.—The Chlorination of Methyl Derivatives of Pyridine. Part I. 2-Methyl Pyridine: W. J. Sell.—The Absorption Spectra of Uric Acid, Murexide and the Ureides in Relation to Colour and to their Chemical Structure: W. N. Hartley.—Further Studies on Dihydroxymaleic Acid: H. J. H. Fenton.—The Thermal Decomposition of Formaldehyde and Acetaldehyde: W. A. Bone and H. L. Smith.—The Synthesis of Formaldehyde: D. L. Chapman and A. Holt, Jun.—The Influence of Light on Diazo-reactions. Preliminary Notice: K. J. P. Orton, J. E. Coates, and (in part) F. Burdett.

THURSDAY, MAY 18.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On Lesage's Theory of Gravitation and the Repulsion of Light: Prof. G. H. Darwin, F.R.S. The Atomic Weight of Chlorine; an Attempt to Determine the Equivalent of Chlorine by burning with Hydrogen: Prof. H. B. Dixon, F.R.S., and E. C. Edgar.—The Flow of the River Thames in Relation to British Pressure and Rainfall: Sir Norman Lockyer, K.C.B., F.R.S., and Dr. W. J. S Lockyer.—Thorianite, a New Mineral, from Ceylon: Prof W. R. Dunstan, F.R.S., and G. S. Blake.—The Elastic Properties of Steel at High Temperatures: Prof. B. Hopkinson and F. Rogers.—Modified Apparatus for the Measurement of Colour, and its Application to the Determination of the Colour Sensations: Sir William de W. Abney, K.C.B., F.R.S.—Further Observations on the Germination of the Seed of the Castor Oil Plant (*Ricinus communis*): Prof. J. Reynolds Green, F.R.S., and H. Jackson.—On the Efferent Relationship of the Optic Thalamus and Deiter's Nucleus to the Spinal Cord, with Special Reference to the Cerebellar Influx Theory (Hughlings Jackson) and the Genesis of Decerebrate Rigidity (Sherrington): Dr. F. H. Thiele.—On Reciprocal Innervation of Antagonistic Muscles. Eighth Note: Prof. C. S. Sherrington, F.R.S.—The Structure and Function of Nerve Fibres: Prof. J. S. Macdonald.—On the Occurrence of Anopheles (Myzomyia) Listoni in Calcutta: Major A. Alcock, C.I.E., F.R.S., and Major J. R. Adie.

ROYAL INSTITUTION, at 5.—Flame: Sir James Dewar, F.R.S.

SOCIETY OF ARTS, at 4.30.—Plague in India: Dr. C. Creighton.

FARADAY SOCIETY, at 8.—An Application to Electrolytes of the Hydrate Theory of Solutions: T. M. Lowry.

FRIDAY, MAY 19.

ROYAL INSTITUTION, at 9.—The Native Races of the British East Africa Protectorate: Sir Charles Eliot, K.C.M.G.

EPIDEMIOLOGICAL SOCIETY, at 8.30.

SATURDAY, MAY 20.

ROYAL INSTITUTION, at 3.—The Evolution of the Kingship in Early Society: Dr. J. G. Frazer.

THE BIRDS OF CENTRAL AMERICA.

Biologia Centrali-Americana. Aves. By Osbert Salvin, M.A., F.R.S., and Frederick Ducane Godman, D.C.L., F.R.S. 4 vols. (London: 1879–1904.)

CONGRATULATIONS to the surviving author of these volumes must be mingled with deep condolence that his long-tried coadjutor and comrade should not have been spared to complete this portion of the great work in which they were jointly engaged, and to supply that summary of its contents which he, perhaps, alone could have written. But acutely as the loss of Mr. Salvin is to be lamented, if on no other account than this, no less real is the gratification with which the bringing to an end of a task that has lasted for a quarter of century is to be regarded, and the relief to Mr. Godman's mind at the accomplishment of another portion of his gigantic design must be enormous. It is getting on for twenty years since the volume treating of the mammals of Central America was reviewed in these pages by the late Sir William Flower (NATURE, xxxiv., p. 615, October 28, 1886), and that portion also suffered by the untimely death of its author, Mr. Edward R. Alston, so that instead of the comprehensive view of the mammalian fauna of the country which he had intended to appear in the introduction to the volume, we had merely a series of tables of distribution which he had prepared to found that view upon, and these tables Mr. Sclater, who prefixed a few prefatory sentences, left to speak for themselves. Speak for themselves they did, but they needed an interpreter, since they were drawn up for the most part on geographical lines—or, to be more accurate, from a politico-geographical base, the geographical element preponderating.

The tables given in the first of the volumes treating of birds, and now before us (being almost identical in form with those contained in the "Introduction"[1] to the first volume on Lepidoptera), do not differ very greatly in character, though herein the political divisions of the country are given in greater detail, so as to be more important than the geographical. Now each of these methods unquestionably has its advantages—mostly of a practical kind. If we want to see or obtain examples of any particular kind of animal, it is convenient to know where it may be found. But it can hardly be doubted that, had Mr. Salvin lived, he, with his experience of the country and its ornithology, would scarcely have been content without trying if it were not possible to treat the distribution of the species, genera, and families as well from a physical point of view. That he was fully aware of the importance of taking that aspect of the question is shown by the pithy remarks on the subject in an article published by Mr. Godman and himself in *The Ibis* for 1889 (p. 242)—several years, be it observed, after the appearance of Mr. Alston's tables. The labour, no doubt, would have been immense, and only to be performed by one possessed of such knowledge, alike minute and wide, as Mr. Salvin had; but assuredly he was convinced that it can never be too strongly impressed upon all students of topographical distribution that the key to the subject lies in the physical features of the country, especially of a tropical country of such varied character as Central America. Even an indication of the rough division into the three well known zones—the *tierra caliente*, the *tierra templada*, and the *tierra fria* would be better than nothing, though in a country extending over so many degrees of latitude and of such diverse heights, what is the *tierra templada* of one district becomes the *tierra fria* of another.

At the same time, it must be admitted that more than this is required. Comparative altitudes and the extent of forest-growths may explain some things, but they will not account in all cases for the limits of the area to which a certain form, say Pharomacrus or Oreophasis, may be confined. But if boundaries are not to be accounted for by physical characters, assuredly they can be still less rationally explained on political or geographical grounds. Considerations of this kind seem to point to the futility of attempting to lay down any boundaries at all, unless those that are physical can be traced, and of course the difficulty of tracing them is sometimes very great. To take a familiar instance here at home. Who can define on physical grounds, or correlate with them, the distribution of the nightingale in England and Wales? Hence it may be fairly urged that it would be far better for zoologists generally to leave off speaking of areas, regions, subregions, provinces, and the like, and to regard the animal population of a country solely from the faunal point of view.

Central America would seem especially to lead to some such conclusion as this. It can hardly be doubted that the existing fauna of America—North and South—is the result of at least three perfectly distinct faunas, which have originated in, or been derived from, as many different tracts, and probably at as many different epochs. In Central America all three meet, though one is overwhelmingly out of proportion to the other two. This is practically identical with the fauna of by far the greater part of South America as distinguished from that of Patagonia, which seems to have had a very different origin and history, while the former is equally distinct from that which prevails now over the greater part of North America—this last being, as Prof. Huxley long ago intimated (*Proc. Zool. Soc.*, 1868, p. 314), much more closely allied to the Palæarctic fauna, if, indeed, he might have added, it be not substantially of Palæarctic extraction. Then again, while comparatively few of the members of the fauna now dominant in Central and the greater part of South America have penetrated to the area at present occupied by the apparently much more ancient Pata-

[1] That "Introduction" also contains a succinct description, excellent so far as it goes, by Mr. Godman, of the natural features of each political district of Central America, which is taken to include the whole of Mexico from the Rio Grande and the Rio Gila, but excluding Lower California, and thence to the Isthmus of Darien in the now independent State of Panama. The subject has been much more elaborately treated, though of course with especial reference to the flora of the country, by Mr. Hemsley in his admirable "Appendix" to the fourth volume of the "Botany" of the whole work (pp. 138–170).

gonian fauna in the extreme south, a considerable portion have invaded North America—possibly re-occupying the home whence they had been driven during some glacial period, but certainly to an extent that sensibly affects the existing fauna. In the same way certain characteristic forms of the Patagonian fauna, diminishing in number as the distance from their modern focus increases, occur throughout the whole length of South America, generally clinging to the slopes of the Andes, and a few reach the highlands of Central America—Scytalopus, for instance, the sole example of that most characteristic Patagonian family, Pteroptochidæ, which has made its way into Costa Rica.

Further into detail it would be impossible here to go, for it would need the exhibition of long lists and tables showing the distribution of various groups or forms to make clear the truth of the statements just enunciated, to which, no doubt, some will demur; but it may be mentioned that their truth does not rest alone on the evidence afforded by birds, for a close examination of the other classes of vertebrates will be found to corroborate the same position, and it may be left for time to show whether the opinions here expressed are not generally accepted as true. Briefly recapitulated, they are that the whole of America is now occupied by three faunas. The very ancient and, it may be added, morphologically low Patagonian in the south; that of a somewhat higher morphological rank which peoples the greater part of South America, all of Central America, and permeates almost to the middle of North America, until it is outnumbered by still higher forms derived from a Palæarctic stock; but to lay down any boundaries, even physical boundaries, for these distinct faunas is impossible, and though we may call the first and last "Patagonian" and "Nearctic" respectively, it is not easy to find a good title for the second, unless we were to apply to it Mr. Sclater's original name, "Neotropical," restricting that in the southern direction and extending it in the northern. It has been called "Columbian" by one writer, and if that epithet had not been used before in a much more limited sense by another writer the name would not be inappropriate, for Colombia may be regarded as its modern focus, but doubtless it anciently extended much further to the northwards, and by it in remote times the Sandwich Islands were most likely colonised.

If these remarks be deemed too critical, it must be understood that they are not intended to be generally opposed to the views of Mr. Godman. Writing of the butterflies in the "Introduction" before referred to, he stated expressly that the fauna of Central America "is mainly a northern extension of that of tropical South America," with a considerable number of Nearctic forms "coming down the central plateau a certain distance into Mexico, and some even into Guatemala." This is not only equally true of the birds, but the southern extension of their northern forms reaches even further. The real question is, what value is to be attached to these northern forms? A very slight examination will show that nearly all belong to families that are essentially Neotropical. It has been pointed out before now that the so-called Nearctic "Region" has not more than one peculiar family of birds (Chamæidæ), and that a very doubtful one. All the other families of land-birds are either Neotropical or Palæarctic, so that in one sense it may be said that no distinct, or peculiar, Nearctic fauna exists, the bird-population of North America having (with that one doubtful exception) wholly Palæarctic or Neotropical affinities, and those often of the very closest nature. No stronger corroboration of the views of Prof. Huxley, Prof. Heilprin, and others who have advocated the abolition of the Nearctic "Region" can be adduced than is furnished by Mr. Godman's tables, and when we speak of a Nearctic fauna, such as exists now, we mean a mixed multitude of either Neotropical or Palæarctic extraction, or having a common origin with one or the other of those faunas.

But it will not do here to follow further this interesting theme, important as it is in the light that it sheds on the history of the modern inhabitants of the earth. Something must be said before we leave these volumes of the way in which they are presented to the public. Considering that upwards of 1400 species of birds had to be included, the amount of space available for the treatment of each must necessarily be small. But here a most rigid and commendable economy has been practised. No space is needlessly taken up by considerations of taxonomy, nomenclature, or such like ancillary subjects on which so many faunal writers deem it expedient to dilate, though the first is only wanted in a general treatise and the second is regarded by the wise as a snare to be avoided by all who have no time to waste over frivolities. By many of the younger zoologists of the present day the principle of nomenclature followed by the authors will be set down as old-fashioned, but considering the weight of the authorities cited, and their number, the application of the principle is abundantly justified, though exception to some of the results may here and there be reasonably taken, and sufficient synonymy is given as to preclude any possible confusion. In like manner there is no attempt to invent a new classification, for which, in the present state of flux, all should be thankful. That which has been in use by taxonomers for some thirty years in respect to American, or at least South American, birds is adopted. Be its faults what they may, it is well understood by the great majority of those who have been most interested in the subject during that period. The localities whence each species has been recorded are duly noted in the account of it, and thus the details of its range may in most cases be very fairly traced, while reference is systematically made to the authority responsible for the statement, and this, needless to say, is a very important matter. Furthermore, the distinguishing characters of both genera and species are presented with the skill that comes only from intimate knowledge of the respective forms and careful comparison of them with their allies, a feature that is often absent in modern ornithological works, and in one of this magnitude is especially to be commended. The species

figured, one hundred and fifty in number, seem to have been well selected, and the plates in which they are represented by Mr. Keulemans are in the style which has won him so much reputation as an ornithological artist. But all these merits pale before the admiration which the bold conception and patient execution of this grand undertaking excites. There is no English work on natural history comparable in these respects with the "Biologia Centrali-Americana," and the only foreign one which it calls to remembrance is the marvellous "Madagascar" of the late M. Grandidier. The debt due by naturalists of all branches and of all countries to the enterprise, the zeal, and the perseverance of both Messrs. Salvin and Godman, and to the munificence of the latter, for without that all the rest would have availed little or nothing, is one that can never be repaid. A. N.

VECTOR MECHANICS.

Die Grundlagen der Bewegungslehre von einem modernen Standpunkte aus. By Dr. G. Jaumann. Pp. vi+422. (Leipzig: J. A. Barth, 1905.)

THIS work is intended as a systematic general introduction to mechanics; as in the recent English exposition of Webster, the whole field of solid and deformable bodies is considered, so that the book has a wide range—a feature which must necessarily be purchased to some extent at the expense of depth.

Dr. Jaumann, following a method which now enjoys some popularity on the Continent, treats the subject by vectorial methods throughout. The first chapter introduces the ideas of velocity and acceleration, and with them the ideas of the vector and the scalar and vector products of two vectors. This is very natural and well written; it is, however, followed by the introduction of dyads, which was scarcely to be expected at this early stage of the work; and when the author, as is the habit of those writers who apply vectors, takes the liberty of making some additions to the vector calculus itself, and plunges us forthwith into an able but somewhat difficult discussion of "rotary" dyads, we are thrown into doubt as to the class of readers for whom the book is designed.

After this we come back to the ideas of partial and absolute acceleration, illustrated by astronomical considerations, and to the conception of gravitation, with an account of Kepler's laws. This closes the first section of the book, which, though interesting, leaves an unsatisfied and helpless feeling behind it, for the student (if the book is written for students) has not learnt how to find for himself the path of a point in a given field of acceleration, which is surely the main problem of this part of the subject. Thus, although Foucault's pendulum is described, the theory of it—which would make no greater demand on the mathematical capacity of the reader than the rotary dyads require—is not worked out.

The author now introduces the idea of mass, which is defined (as in most good modern works) by means of what used to be called the principle of action and reaction; in other words, the ratio of the masses of two particles is defined as the ratio of the accelerations which they induce in each other when moving under each other's influence, and the idea of "force" is altogether abandoned. These ideas are again supplemented by astronomical illustrations, even the tides being worked into the scheme; and after this we have more vector calculus, with Stokes's theorem in the vector notation.

Dr. Jaumann next discusses rigid bodies, rigidity itself being defined by a vector equation! He discusses the constants of inertia, and solves some very elementary problems, and then passes on to a sketch of acoustics.

The last principal division of the book deals with deformable media—elastic solids, liquids, and gases. The treatment here is good so far as it goes, but too slight to be very satisfying.

Considering the work as a text-book, it must be said that the difficulty of the vectorial methods so freely used is hopelessly out of proportion to the results achieved. The student who has mastered the whole machinery of the treatise will still be unable to solve for himself any but the most rudimentary of the actual problems of dynamics. The author seems to overlook the cardinal fact that the solution of every moving material system depends ultimately on the integration of the associated differential equation, or some equivalent process, and that this is the really difficult part of the subject, the rest being child's play in comparison. A book which devotes scores of pages to symbols and formulæ, and yet never brings the reader into close grip with this essential kernel of the subject, is open to the charge of beating about the bush.

GREATER AUSTRIA.

Geologie der Umgebung von Sarajevo. By Ernst Kittl. Part iv. of the *Jahrbuch der k.k. geologischen Reichsanstalt* for 1903. (Vienna: R. Lechner, 1904.)

THIS general essay, with its plates of fossils and numerous geological sections in the text, corresponds to one of the memoirs on special districts issued by our own Geological Survey. It includes, moreover, a folded geological map on the scale of 1:75,000, and is thus a complete guide for future scientific visitors. The map itself reminds us of the charm of the Bosnian capital, set in its semicircle of craggy hills, where the gorge of the Miljačka broadens out towards the alluvial basin of Ilidže. We trace the mountain-road from the Ivan Pass coming out suddenly on this cultivated plain, and see again the minarets of Sarajevo shining like white masts under the background of Triassic precipices.

The author's introduction shows how the geological survey by Austrian observers followed hard upon the capture of the city, which had risen fanatically to arms. The famous ammonite-locality of Han Bulog, on the way to Mokro, was thus discovered as early as 1880; and the important part played by Triassic rocks east of Sarajevo was made known by

Bittner and Kellner, and in 1892 by the author, who was sent by von Hauer to collect for the museum in Vienna. The whole Alpine Trias seems well represented near the city, some of the massive limestones, rich in Diplopora, being spoken of as "Riffkalke." The red limestone with Ptychites, the rock best known in our collections, is on an Upper Muschelkalk horizon. While the Eocene period is probably represented by a Flysch-facies, the Oligocene and Miocene lagoons and freshwater lakes show that the mountain-land of Bosnia was rising above the sea in Middle Cainozoic times.

The author's detailed descriptions of the region, district by district, are illustrated by sections drawn on a correct vertical and horizontal scale, and by occasional sketches and photographic views. As a type of the sketches, we may mention the effective Fig. 16 (p. 611), showing the rounded forms of the Flysch deposits banked and sometimes faulted against the scarped Triassic masses to the east. Another section (p. 639) shows well how the Flysch strata, extending north towards Doboj and the great Hungarian plain, have been tilted and overfolded during the orogenic movements of the Dinaric Alps, which continued, as we now know, far into Pliocene times. The steep forms of the lowland landscape, cut into by frequent streams, are readily appreciated from the section.

The palæontological portion of the memoir records fossils from the "Kulmschiefer," including, curiously enough, *Modiola lata*, described by Wheelton Hind as recently as 1896. The author supports (p. 671) E. Haug and J. P. Smith in restoring Goniatites as a restricted generic term, so that we again have *Goniatites crenistria* and *truncatus*, as well as *sphaericus* and *striatus*. Osmanoceras and Tetragonites are described as new genera of goniatites. The Bellerophon-beds of the Upper Permian yield, amid a fairly rich fauna, Promyalina, a new member of the Aviculidæ. These forms, and a number of new species, are suitably figured, either in the text or in the plates. It is pleasant to recall the bookshops in Sarajevo on the way to the bazaar and the river-side, where this last product of Austrian investigation will appear for sale under the shadow of the Sultan's mosque.

G. A. J. C.

ECONOMIC SCIENCE.

Economic Essays by Charles Franklin Dunbar. Edited by O. M. W. Sprague, with an introduction by F. W. Taussig. Pp. xvii+372. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1904.) Price 10s. 6d. net.

NO American economist has been held in higher repute for judiciousness, breadth of view, and "soundness" than Charles Franklin Dunbar, professor of political economy at Harvard from 1871 until his death in 1900, sometime Dean of the college (between 1876 and 1882), and later Dean of the faculty of arts and sciences. But his output was never extensive, perhaps because the university teaching of political economy was not his first choice, or at any rate not his first calling. It was not until Prof. Dunbar had attained the ripe age of forty-one that he was appointed to his professorship at Harvard. Previously he had engaged in newspaper work, and had edited between 1859 and 1869 the *Boston Daily Advertiser*. To the work of the editorship of this paper Prof. Dunbar returned for a brief space to fill a breach at a time of crisis in 1884.

Having taken to the profession of teaching after engaging in practical affairs and feeling the excitements of politics, it is somewhat remarkable that Prof. Dunbar's interests after his appointment at Harvard should have been "academic" to so exclusive an extent. He studiously avoided making contributions to magazines upon the economic aspects of current events, and appears to have held that it was the main duty of the economist to trace the leading trends of social forces rather than to spend his energies in directing minor circumstances. Prof. Dunbar's best known work was done upon the subject of banking, and we are told by Prof. Taussig in his introduction to this collection of his late colleague's economic essays that he had meditated a comprehensive treatise relating to America upon the wider subject of which banking is a part, namely, financial history. Prof. Dunbar's little "History of Banking" is read to-day by all students of economics of this country and the United States at least.

The collection of essays before us contains a good deal of material that was not easily accessible previously, and some matter that is now published for the first time, upon the range of subjects which Dunbar made peculiarly his own. Eight out of the twenty essays included deal specifically with banking, and some of them are valuable contributions to our knowledge of the history of banking—for instance, the two dealing with early banking schemes in England and the Bank of Venice. Eight more essays are concerned more particularly with finance, for example, analyses of certain crises, the examination of the direct tax of 1861, and the discussion of the precedents followed by Alexander Hamilton. The remaining four essays arose out of the author's other chief interest, namely, the literature of classical economics; they are entitled "Economic Science in America, 1776–1876," "The Reaction in Political Economy" (written in 1886), "The Academic Study of Political Economy," and "Ricardo's Use of Facts." Certain of these essays were executed so long ago as almost to have become themselves a part of the old literature of classical economics; but, taken as a whole, they will prove enlightening even to economists who have benefited from the analysis effected and researches carried out since Prof. Dunbar's discussions appeared, for without exception the essays collected in this volume are thorough, scholarly, well pondered, and finely proportioned. Prof. Sprague's work of editorship appears to have been done admirably. All students of economics will be grateful to him for having made a collection of Prof. Dunbar's scattered writings and brought to the press the work which he left behind in manuscript.

OUR BOOK SHELF.

Beiträge zur Physik der freien Atmosphäre. Edited, with the cooperation of a number of distinguished meteorologists, by R. Assmann (Berlin) and H. Hergesell (Strassburg). Vol. i. Part i. (Strassburg: Trübner, 1904.)

ON receiving the first number of a new periodical, the question of the need and room for such a publication first rises to one's thoughts. It must be admitted that it is not easy to see the necessity for a magazine so highly specialised as the one before us. That the investigation of the upper atmosphere is a separate branch of study in itself is very questionable; and there are already the *Meteorologische Zeitschrift*, the *Veröffentlichungen der internationalen Kommission für wissenschaftliche Luftschiffahrt,* and the *Illustrierte Aëronautische Mitteilungen,* all suitable for the discussion of such investigations.

The subject-matter of this first number of the *Beiträge* is exceedingly interesting, and of no little importance. It contains three articles, each by a high authority on the subject dealt with.

The first, by Prof. Hergesell, is devoted to proving that kites can be raised to great heights quite independently of the weather conditions where a large expanse of water and a high-speed motor-boat are at the disposal of the observer, this being the same result as that arrived at by Rotch and by Dines. The more immediate object of the present article is to urge the possibility and necessity of founding an observatory on Lake Constance specially devoted to the investigation of the upper atmosphere.

In the second article Prof. Assmann describes "a year's simultaneous kite ascents in Berlin and Hamburg," with special reference to the existence of a warm current of air flowing almost constantly between 500 metres and 1000 metres above the surface. That such a current should exist is very interesting, and further observations as to its extent, strength, and permanency are very much to be desired.

The remaining article treats of the methods employed by Dr. A. de Quervain in determining the paths traversed by balloons sent up with registering instruments only. The methods described can only be employed so long as the balloon remains within the range of vision of a telescope; they are really trigonometrical. The first is the simple method of two theodolites at the ends of a base line, and the second similar, with the exception that only one theodolite is used, the heights of the balloon at the moments of observing with the theodolite being obtained later from the curve drawn by the barograph carried with the balloon.

Articles for future numbers, which are to be published as may be found convenient, are promised by Prof. Sprung, Prof. Wiechert, Dr. J. Maurer, and Dr. A. de Quervain. G. C. S.

The Inventor's Guide to Patent Law and the New Practice. By James Roberts, M.A., LL.B. Pp. viii+109. (London: John Murray, 1905.) Price 2s. 6d. net.

THIS is a well written handbook on British patent law and practice in which the inventor will find information of use to him. The new practice referred to in the title is the search by officials of the Patent Office for anticipations within the fifty years prior to an application, and the possible enforced statement as to these which the patentee may have imposed upon his own specification.

While the information derived from a search by officials of the Patent Office may be of the greatest use to a patentee, there is considerable doubt as to the advantage either to the patentee or to the community of allowing what may in reality be a specification of a valuable invention to be marred by an official statement as to certain prior specifications. There is a fear that an official with insufficient experience of practice either in works or in the Chancery Court may attach too great importance to what are known as paper anticipations, and by insisting on referring to them prevent a patent which otherwise might have been the basis of a successful manufacturing process, and be good enough to stand attack in the courts, from being even looked at by any manufacturer. However this may be, it is impossible to cast any doubt upon the Patent Office without paying a tribute to the great courtesy with which the humblest stranger who goes there is met, and the help that he is sure to receive short of professional advice. The library, too, and its arrangement is an admirable feature.

References to large standard works on patent law are very numerous, and will be of great service to the reader who desires more detailed information on difficult points than can possibly be given in a moderate compass. B.

A Manual of Mining. By M. C. Ihlseng and E. B. Wilson. Fourth edition. Pp. xvi+723. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 21s. net.

BASED on the course of lectures delivered at the School of Mines of Colorado, Prof. Ihlseng's book, which is regarded in America as the best text-book on the subject, has been enlarged under the joint authorship of Mr. Wilson to include coal mining, which received scant attention in previous editions. Excepting that ore dressing and coal washing are not touched upon, it now covers much the same ground as Sir C. Le Neve Foster's "Elements of Mining and Quarrying." The arrangement is, however, altogether different. The book is divided into two parts, mining engineering and practical mining. The former deals with prospecting, preparatory work, methods of mining, power generation, hoisting machinery, electric generation and water power, hoisting machinery and underground conveyances, underground haulage systems, wire rope transmission, the compression of air, pumping, mine gases, ventilation, distribution of air, the illumination of mines, and accidents in mines.

The second part deals with shafts, sinking in running ground, timbering, driving drifts, tunnels and gangways, drilling and boring machines for explorations, miners' tools, channelers, drills and coal-cutters, and blasting. It is difficult to see the object of this division into mining engineering and practical mining. In this country it is not usual to draw a sharp distinction between theory and practice in engineering work. Moreover, the order of the chapters in each section does not appear to be so logical as that followed in English and Continental text-books. Thus on p. 30 the steam shovel is described, but it is not until p. 621 that we come to a description of the ordinary pick and shovel. On p. 47 the blasting of coal is dealt with, but it is not until p. 685 that the operation is described and the theory of blasting explained. The book contains much useful information, but the lack of method in the arrangement cannot fail to militate against its use as a text-book. The illustrations, many of which are excellent, are largely borrowed from makers' catalogues, and are not nearly so useful for educational purposes as rough sketches specially drawn would be.

The frequent misprints in figures in the index and in the references should have been carefully guarded against in a book intended for students. Several

names also are incorrectly printed, and the references given at the end of the chapter on mine illumination mostly refer to ventilation. On p. 681 the student is taught to load a hole "with nitroglycerine by pouring from a tin cup upon the fuse with its cap and covering the mass with water." Evidently the Coal Mines Regulation Act has no analogue in a country where, as the authors point out, "each new camp, untrammelled by tradition to keep it in the rut of prejudice, displays its genius for organisation and absorbs the latest devices, tried and true."

The Practical Photographer. (Library Series.) Edited by Rev. F. C. Lambert. No. 16, *Pictorial Composition.* Pp. xx+64. No. 17, *Animal Photography.* Pp. xxiv+64. (London: Hodder and Stoughton, 1905.) Price 1s. net.

In the first of these books the editor gives an interesting account of the pictorial work of Bernard Alfieri, illustrating it with six excellent reproductions of this well-known worker's studies. Among the other sections of the book, which are written by various authors, those on the principles of composition, by Arthur Burchett, and some notes on composition in landscape, by Horace Mummery, will be found of great practical value. In these the pen and ink sketches showing the several methods of producing balance in pictures call for special attention. Other articles, such as that on the arrangement of the foreground, are well worth perusing. Numerous well reproduced illustrations, serving as examples of good and bad composition, accompany the text. The second of the above books appeals to another class of photographers, for, with the exception of the editor's article on the pictorial work of Viscount Maitland, it is devoted to the photography of animals. Like the former book; numerous authors have contributed to the text, and a very wide range of points of view is included. It is written on the same practical lines, and is accompanied by fifty-five well selected illustrations. Both volumes will add to the value of this useful library series.

Détermination des Espèces minérales. By L. M. Granderye. Pp. 184. (Paris: Gauthier-Villars, n.d.) Price 2.50 francs.

In this little book, which is a publication of the "Encyclopédie scientifique des Aide-Mémoire," the author has apparently attempted to devise a royal road for the determination of a mineral species. For this purpose he has compiled a number of lists of the more common minerals arranged according to physical characters, viz. crystal-system, colour, structure, density, &c., and has supplemented these with some instructions on blowpipe analysis and chemical examination in the dry way. Such lists are certainly of great value for determination purposes, but, as regards the more common minerals, at any rate, it would be a mistake to encourage the student to rely upon any methodical scheme of determination to the neglect of an acquisition of a thorough knowledge of the characters of the individual species. For many minerals, especially with imperfectly crystallised specimens, we fear these tables would prove an uncertain guide in the absence of any observations of the optical characters or of chemical examination in the wet way. In Brush and Penfield's standard work on determinative mineralogy it is true that no account is taken of the optical characters, but sufficient importance is given to chemical tests in the wet way. The tables are not altogether free from errors and misprints; thus a saline taste is attributed to sodalite, rhodonite is described as a carbonate, and the density of wolframite is given as 5·5 on one page and 7·5 on another. The book concludes with a list of 600 minerals with their principal characters, viz. density, hardness, &c.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Dynamical Theory of Gases and of Radiation.

I AM glad to have elicited the very clear statement of his view which Mr. Jeans gives in NATURE of April 27. In general outline it corresponds pretty closely with that expressed by O. Reynolds in a British Association discussion at Aberdeen (NATURE, vol. xxxii. p. 534, 1885). The various modes of molecular motion are divided into two sharply separated groups. Within one group including the translatory modes, equipartition of energy is supposed to establish itself within a small fraction of a second; but between the modes of this group and those of vibration included in the other group, equipartition may require, Mr. Jeans thinks, millions of years. Even if minutes were substituted for years, we must admit, I think, that the law of equipartition is reconciled with all that is absolutely proved by our experiments upon specific heat, which are, indeed, somewhat rough in all cases, and especially imperfect in so far as they relate to what may happen over long intervals of time.

As I have already suggested, it is when we extend the application of the law of equipartition to the modes of æthereal vibration that the difficulties thicken, and this extension we are bound to make. The first question is as to the consequences of the law, considered to be applicable, after which, if necessary, we may inquire whether any of these consequences can be evaded by supposing the equipartition to require a long time for its complete establishment. As regards the first question, two things are at once evident. The energy in any particular mode must be proportional to θ, the absolute temperature. And the number of modes corresponding to any finite space occupied by the radiation, is infinite. Although this is enough to show that the law of equipartition cannot apply in its integrity, it will be of interest to follow out its consequences a little further. Some of them were discussed in a former paper,[1] the argument of which will now be repeated with an extension designed to determine the coefficient as well as the law of radiation.

As an introduction, we consider the motion of a stretched string of length l, vibrating transversely in one plane. If a be the velocity of propagation, ξ the number of subdivisions in any mode of vibration, the frequency f is given by

$$f=a\xi/2l \quad . \quad . \quad . \quad . \quad . \quad . \qquad (1)$$

A passage from any mode to the next in order involves a change of unity in the value of ξ, or of $2lf/a$. Hence if e denote the kinetic energy of a single mode, the law of equipartition requires that the kinetic energy corresponding to the interval df shall be

$$2le/a.df \quad . \quad . \quad . \quad . \quad . \quad . \qquad (2)$$

In terms of λ the wave-length, (2) becomes

$$2le/\lambda^2.d\lambda \quad . \quad . \quad . \quad . \quad . \quad . \qquad (3)$$

This is for the whole length of the string. The longitudinal *density* of the kinetic energy is accordingly

$$2e/\lambda^2.d\lambda \quad . \quad . \quad . \quad . \quad . \quad . \qquad (4)$$

In each mode the potential energy is (on the average) equal to the kinetic, so that if we wish to reckon the whole energy, (4) must be doubled. Another doubling ensues when we abandon the restriction to one plane of vibration; and finally for the total energy corresponding to the interval from λ to $\lambda+d\lambda$ we have

$$8e/\lambda^2.d\lambda \quad . \quad . \quad . \quad . \quad . \quad . \qquad (5)$$

When we proceed to three dimensions, and consider the vibrations within a cube of side l, subdivisions may occur in three directions. In place of (1)

$$f=a/2l.\sqrt{(\xi^2+\eta^2+\zeta^2)} \quad . \quad . \quad . \quad . \qquad (6)$$

where ξ, η, ζ may assume any integral values. The next step is to ascertain what is the number of modes which corresponds to an assigned variation of f.

If the integral values of ξ, η, ζ be regarded as the

[1] "Remarks upon the Law of Complete Radiation," *Phil. Mag.*, xlix. p. 539 June, 1900.

coordinates of a point, the whole system of points constitutes a cubic array of volume-density unity. If R be the distance of any point from the origin,

$$R^2 = \xi^2 + \eta^2 + \zeta^2;$$

and the number of points between R and R+dR, equal to the included volume, is

$$4\pi R^2 dR.$$

Hence the number of modes corresponding to df is

$$4\pi(2l/a)^3 f^2 df,$$

or in terms of λ

$$4\pi . 8l^3 . \lambda^{-4} d\lambda \quad . \quad . \quad . \quad . \quad . \quad . \qquad (7)$$

If e be the kinetic energy in each mode, then the kinetic energy corresponding to $d\lambda$ and to unit of volume is

$$32\pi e\lambda^{-4} d\lambda \quad . \quad . \quad . \quad . \quad . \quad . \qquad (8)$$

Since, as in the case of the string, we are dealing with transverse vibrations, and since the whole energy is the double of the kinetic energy, we have finally

$$128 . \pi . e . \lambda^{-4} d\lambda \quad . \quad . \quad . \quad . \quad . \quad . \qquad (9)$$

as the total energy of radiation per unit of volume corresponding to the interval from λ to $\lambda + d\lambda$, and in (9) e is proportional to the absolute temperature θ.

Apart from the numerical coefficient, this is the formula which I gave in the paper referred to as probably representing the truth when λ is large, in place of the quite different form then generally accepted. The suggestion was soon confirmed by Rubens and Kurlbaum, and a little later Planck (*Drude Ann.*, vol. iv. p. 553, 1901) put forward his theoretical formula, which seems to agree very well with the experimental facts. This contains two constants, h and k, besides c, the velocity of light. In terms of λ it is

$$E\, d\lambda = \frac{8\pi ch}{\lambda^5} \frac{d\lambda}{e^{ch/k\lambda\theta} - 1} \quad . \quad . \quad . \qquad (10)$$

reducing when λ is great to

$$E\, d\lambda = 8\pi k\theta\lambda^{-4} d\lambda \quad . \quad . \quad . \quad . \quad . \qquad (11)$$

in agreement with (9). $E\, d\lambda$ here denotes the volume-density of the energy of radiation corresponding to $d\lambda$.

A very remarkable feature in Planck's work is the connection which he finds between radiation and molecular constants. If N be the number of gaseous molecules in a cubic centimetre at 0° C. and under a pressure of one atmosphere,

$$k = \frac{1 \cdot 013 \times 10^6}{273 N} \quad . \quad . \quad . \quad . \quad . \quad . \qquad (12)$$

Though I failed to notice it in the earlier paper, it is evident that (9) leads to a similar connection. For e, representing the kinetic energy of a single mode at temperature θ, may be identified with one-third of the average kinetic energy of a gaseous molecule at that temperature. In the virial equation, if N be the total number of molecules,

$$\tfrac{3}{2}pv = \Sigma \tfrac{1}{2} m V^2 = 3Ne,$$

so that

$$e = pv/2N \quad . \quad . \quad . \quad . \quad . \quad . \qquad (13)$$

If we apply this to one cubic centimetre of a gas under standard conditions, N has the meaning above specified, $v = 1$, and $p = 1 \cdot 013 \times 10^6$ C.G.S. Accordingly, at 0° C.

$$e = 1 \cdot 013 \times 10^6 / 2N,$$

and at θ°

$$e = \frac{1 \cdot 013 \times 10^6 \times \theta}{2 \times 273 N} \quad . \quad . \quad . \quad . \qquad (14)$$

Introducing this into (9), we get as the number of ergs per cubic centimetre of radiation

$$\frac{64 . \pi . 1 \cdot 013 . 10^6 . \theta . d\lambda}{273 . N . \lambda^4} \quad . \quad . \quad . \qquad (15)$$

θ being measured in centigrade degrees. This result is eight times as large as that found by Planck. If we retain the estimate of radiation used in his calculations, we should deduce a value of N eight times as great as his, and probably greater than can be accepted.

A critical comparison of the two processes would be of interest, but not having succeeded in following Planck's reasoning I am unable to undertake it. As applying to all wave-lengths, his formula would have the greater value if satisfactorily established. On the other hand, the reasoning which leads to (15) is very simple, and this formula appears to me to be a necessary consequence of the law of equipartition as laid down by Boltzmann and Maxwell. My difficulty is to understand how another process, also based upon Boltzmann's ideas, can lead to a different result.

According to (15), if it were applicable to all wave-lengths, the total energy of radiation at a given temperature would be infinite, and this is an inevitable consequence of applying the law of equipartition to a uniform structureless medium. If we were dealing with elastic solid balls colliding with one another and with the walls of a containing vessel of similar constitution, energy, initially wholly translational, would be slowly converted into vibrational forms of continually higher and higher degrees of subdivision. If the solid were structureless, this process would have no limit; but on an atomic theory a limit might be reached when the subdivisions no longer included more than a single molecule. The energy, originally mechanical, would then have become entirely thermal.

Can we escape from the difficulties, into which we have been led, by appealing to the slowness with which equipartition may establish itself? According to this view, the energy of radiation within an enclosure at given temperature would, indeed, increase without limit, but the rate of increase after a short time would be very slow. If a small aperture is suddenly made, the escaping radiation depends at first upon how long the enclosure has been complete. In this case we lose the advantage formerly available of dividing the modes into two sharply separated groups. Here, on the contrary, we have always to consider vibrations of such wave-lengths as to bear an intermediate character. The kind of radiation escaping from a small perforation must depend upon the size of the perforation.

Again, does the postulated slowness of transformation really obtain? Red light falling upon the blackened face of a thermopile is absorbed, and the instrument rapidly indicates a rise of temperature. Vibrational energy is readily converted into translational energy. Why, then, does the thermopile not itself shine in the dark?

It seems to me that we must admit the failure of the law of equipartition in these extreme cases. If this is so, it is obviously of great importance to ascertain the reason. I have on a former occasion (*Phil. Mag.*, vol. xlix. p. 118, 1900) expressed my dissatisfaction with the way in which great potential energy is dealt with in the general theory leading to the law of equipartition. RAYLEIGH.

May 6.

The Cleavage of Slates.

IN his critique of Dr. Becker's theory of slaty cleavage in NATURE of May 4, "A. H." says that it is substantially the same as mine, and rightly objects that, "if the cleavage plane were a plane of shearing it would correspond with a circular section of the ellipsoid" of distortion. It is true that I made that suggestion in the body of my first paper on cleavage in the *Geological Magazine*, 1884, but in a postscript to that paper I stated that a conversation with Mr. Harker had led me to the conclusion that the cleavage surfaces are determined by the position of the principal axes of the ellipsoids of distortion produced by a shearing movement, and to this view I have ever since adhered.

"A. H." says that "there are many slates in which the strain ellipsoid is actually presented in deformed spherical concretions or colour-spots." Is this certain? Is it not probable that these discolorations took place after the rock became a slate? In that case the chemical influence emanating from the foreign particle, usually obvious in the centre of the spot, found the greatest conductivity in the direction of the longest axis of the ellipsoid, the next greatest along the mean axis, and very little along the least. It is from this property of little conductivity across the cleavage that slates are eminently suited for roofing. I have a piece of a school slate with two sharply defined oval patches, of each of which the two diameters are 25 mm. and 16 mm. The thickness of the slate is less than 4 mm., and yet the discoloration does not pass through to the other side. If these spots are sections of ellipsoids formed out of spheres by compression, the resulting condensation must have been incredibly enormous. The spots in Borrowdale slates are of a different character from spots of dis-

coloration. They existed in the rock before cleavage was induced. Many of them are broken up like broken egg-shells. Those which are complete lie with their longest axes in the plane of cleavage, and would well agree with the theory that they were deformed along with the enveloping rock by a shearing process, and that the plane of the greatest distortion was the plane of cleavage.

In my paper on cleavage and distortion in the *Geological Magazine* I pointed out that it is to Sir John Herschel that we are indebted for the theory of the "molecular movement," which, I remarked, was in fact a "shear"—a term which has now been universally accepted for this kind of action in rocks; and in my "Physics of the Earth's Crust" I have explained how the crumpling in the harder and cleavage in softer layers of a rock would simultaneously arise from such a shearing movement. O. FISHER.

Harlton, Cambridge, May 8.

A Relation between Spring and Summer.

A FAIR idea of the larger fluctuations of a given meteorological element may be had by means of a two-fold smoothing process, *e.g.* adding the series of values in groups of five (1 to 5, 2 to 6, 3 to 7, &c.), and then doing the same with those sums. In each case the sum is put opposite the middle member of the group.

When this is done with (*a*) the amounts of rainfall in spring (March to May) at Greenwich since 1841, and (*b*) the numbers of warm months in summer (same place and period), we have the two curves in the diagram. The

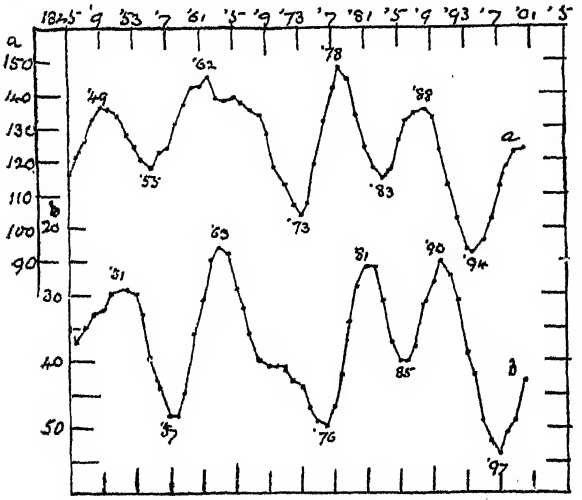

FIG. 1.—Smoothed curves of spring rainfall and summer warmth.

lower one (that for summer) is *inverted*, so that its crests represent *few* warm months, or coolness.

One must be struck, I think, with the similarity of the curves; four long waves (roughly) in each, those of the lower curve lagging in phase somewhat (one to three years) on those of the upper curve. The four *centres of wetness*, as we may call them, of the spring series are followed at a brief interval by four *centres of cold* in the summer series, and the four *centres of dryness* in the former, at much the same interval, by four *centres of warmth* in the latter.

Let us look briefly at the nature of those centres, and we may do so by indicating, first, the character of the group of five springs about each of the dates 1849, 1862, 1878, and 1888 (wave-crests of upper curve), and the corresponding summer groups (wave-crests of lower curve). We find in each group of five springs an excess in the total rainfall, and at least three of the five wet; further, in each summer group a small number of warm months.

5 Springs about	Rainfall	Relation to av.	Wet Springs	5 Summers about	Warm months
1849	28·5	+3·8	3	1851	6 out of 15
1862	28·5	+3·8	3	1863	5 ,,
1878	31·2	+6·5	4	1881	3 ,,
1888	27·9	+3·2	3	1890	3 ,,

Making a similar comparison of the centres of dryness in spring with the centres of warmth in summer, we have:

5 Springs about	Rainfall	Relation to av.	Wet Springs	5 Summers about	Warm months
1855	23·9	−0·8	2	1857	12 out of 15
1873	20·2	−4·5	1	1876	11 ,,
1883	22·3	−2·4	1	1885	10 ,,
1894	15·9	−8·8	0	1897	12 ,,

Here the relations are all of an opposite character.

To what are those long waves of variation to be attributed? And can any physical explanation be given of the sequence which has been indicated? Perhaps some of your readers may be able to throw light on these points. I will only remark that there is no obvious connection with the sun-spot cycle. Thus the first two crests in the upper curve come close after maxima (1848 and 1860), while the two latter are near minima (1878 and 1889).

With regard to the point now reached by this curve (*a*), the rainfall of the present spring (already in excess, May 10) should extend it upwards, but it must apparently be near another crest. Some help in forecasting our summers might perhaps be derived from a consideration of the facts above given. ALEX. B. MACDOWALL.

Fictitious Problems in Mathematics.

IN NATURE of April 27 (vol. lxxi. p. 603) your reviewer finds fault with Cambridge examiners for endowing bodies with the most inconsistent properties in the matter of perfect roughness and perfect smoothness—"A perfectly rough body placed on a perfectly smooth surface." Your reviewer adds, the average college don forgets that roughness or smoothness are matters which concern *two surfaces*, not *one* body.

Will your reviewer give a reference to some page of Whittaker's book (that under review), or to some page of any other text-book used in the last half-century at Cambridge, in support of his charge against Cambridge examiners? Fifty years ago, William Hopkins was still directing the mathematical teaching of Cambridge, and enforcing the conservation of energy where friction is taken into consideration. A perfectly rough sphere moving on a rough surface is intended to mean that, during the motion considered, the sphere rolls without any slip. "A perfectly rough sphere moving on a smooth surface" would no doubt be equivalent to "A sphere moving on a smooth surface"; but where does the phrase occur?

AN OLD AVERAGE COLLEGE DON.

THE alleged inaccuracies of language in stating the assumed conditions of smoothness or roughness prevailing between two bodies in contact are unfortunately so common that it is the exception rather than the rule to find any problem in which these conditions are correctly worded. In working through a chapter of Besant's "Dynamics" with a class the other day, I came across no less than two problems in which a "perfectly rough" body was supposed to be in contact with a second body which in turn rested against a third "perfectly smooth" body. In these cases the framer of the question carefully avoided giving any information as to the roughness or smoothness of the middle body, so that the inaccuracy of language might easily be overlooked. But this does not apply to the following example:—

"A person is placed at one end of a perfectly rough board which rests on a smooth table. Supposing he walks to the other end of the board, determine how much the board has moved. If he stepped off the board, show how to determine its subsequent motion" (Routh, "Elementary Rigid Dynamics," 1882 edition, p. 69, example 4).

At the time of writing the review I was quite unaware that such an example had found its way into a text-book written by so careful a teacher of applied mathematics as Dr. Routh, and it says much for the prevalence at Cambridge of these erroneous forms of statement that this wording failed to attract the author's attention. Since writing my review, it has been brought to my notice that similar inaccuracies widely prevail in the statement of problems involving so-called "perfectly elastic" or "inelastic bodies." THE REVIEWER.

SCIENTIFIC RESULTS OF THE NATIONAL ANTARCTIC EXPEDITION.

THE April number of the *Geographical Journal* contains a series of short papers by members of the *Discovery* Expedition which may be regarded as forming together a kind of "preliminary report" on the work of the expedition in the Antarctic regions. These papers are five in number; Captain Scott deals with the general geography, Mr. Ferrar with physical geography, Lieut. Royds with meteorology, Dr. Wilson with seals and birds, and Mr. Hodgson with the marine biological collections. Captain Colbeck also contributes a paper on the Antarctic sea-ice, discussing the observations made on the *Southern Cross* in 1898–1900 and on the *Morning* in 1902–4.

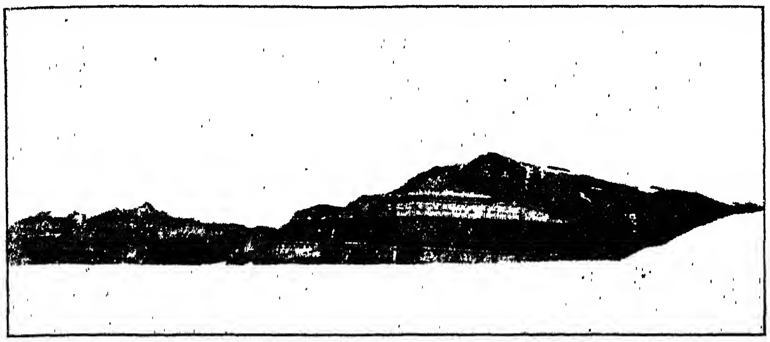

FIG. 1.—Beacon Heights. Sandstone and Basalt.

Without attempting to summarise the contents of each paper, we may try to indicate what are the chief problems which have attracted the attention of the members of the expedition, and what materials they have provided for their discussion. All things considered, perhaps the most important questions concern the remarkable ice conditions observed by Captain Scott and Mr. Ferrar. "There are innumerable glaciers on the coast of Victoria Land," says Captain Scott, "but the great majority merely discharge local *névé* fields lying in the valleys of the coastal ranges. Very few run back to the inland ice, and these may be divided into two classes—the living and the dead. In the long stretch of coast between Cape Adare and Mount Longstaff, over 11° of latitude, there appears to be only four living ice-discharges from the inland." "The Ferrar glacier is typical of the dead glaciers; the ice lies in the valley practically stationary, and gradually wasting away from the summer thawing." "The Ferrar glacier probably contains as much ice as any hitherto known in the world; the Barne and Shackleton glaciers contain a great deal more, and since they are now in such a diminished state it is interesting to think what vast streams of ice they must have been at their maximum." "To what extent the inland ice sheet stood above its present level is also interesting to surmise; one would submit a possibility of 400 or 500 feet."

Again, referring to the Great Barrier, Captain Scott says:—"... the barrier edge sixty years ago was in advance of its present position, in places as much as 20 or 30 miles."

These facts, along with many others, such as observations by Dr. Wilson and Mr. Ferrar of moraines and erratics high above the level of the ice-sheet, all go to show that "the majority of curious and often vast ice-formations met with in the Ross sea must be regarded, not as the result of present day conditions, but as the rapidly wasting remnants of a former age."

One of the most remarkable observations is that while, as just explained, the ice from Victoria Land does not make any important contribution to the ice-barrier in the Ross Sea, that ice is moving northward at the rate of about 600 yards in a year. Captain Scott believes that the greater portion of the ice-sheet in the Ross Sea is afloat, and that the high coast line of Victoria Land continues southward in a direction towards Graham's Land. Here there is obviously a fruitful source of discussion, but whatever the result, with regard to the distribution of land and sea, it may be taken as proved beyond doubt that the ice in at least this part of the Antarctic regions is in a state of fairly rapid retreat, and it is known that the same thing is happening in the Arctic regions.

Mr. Ferrar's geological observations in Victoria Land have an important bearing on the problem of the outline of the land mass, as well as great intrinsic value. In the Royal Society range a gneissic platform was found, probably of Archæan age, and above it in order are granites, sandstone, and basalt. The granites are, according to Mr. Ferrar, of two ages; the sandstone is 2000 feet thick, while the basalt caps the sandstone, forming plateaux which have been dissected by denudation, and probably also broken up by faulting. At the base of the basalt a thin carbon-

FIG. 2.—Mount Erebus with smoke.

aceous seam, not more than one-eighth of an inch in thickness, was found. This seam yielded carbonaceous matter which it is agreed must be due to vegetation, but the plant remains are unfortunately beyond identification.

With regard to questions of climate, it is more necessary to await the full discussion of the observations, but a number of interesting points have already cropped up. The smoke from Mount Erebus blew almost persistently to the east, but every record of the Ross Expedition describes it as going to the west. At the *Discovery's* winter quarters the prevailing winds were south-easterly; the observers are strongly of opinion that this is a local phenomenon. Captain Scott's general conclusions are to the effect that the prevailing direction of the surface winds is west-by-south throughout the winter, and more southerly during summer; and that there is no snowfall except in the summer and on the rare occasions when the wind blows almost due south. These snow-bearing winds were warm, rising to a temperature of 10° C. to 15° C. even in the depth of winter. Their occurrence seems somewhat difficult of explanation, but they obviously have a very important bearing on the relation of temperature and quantity of moisture in causing glacial periods, and modifying their intensity.

In describing the distribution of Antarctic seals, Dr. Wilson records that the Weddell seal was the one most often met with near the land. The expedition made an addition to the list which Dr. Wilson thinks "will prove to be a wanderer from the Southern Ocean islands, representing the now rare sea-elephant of the M'Quaries." Dr. Wilson thinks little of the prospects of the Antarctic seal-fishery, notwithstanding the increased demand for skins of hair-seals, the chief reason being that few skins escape the unsightly scars inflicted by the killer whale. The expedition collected much valuable material with regard to doubtful species of birds, especially cases like the emperor and king penguins and the white-winged and royal albatrosses, where in the adults it is hard to find specific differences, although the chicks are quite distinct.

FIG. 4.—Emperor Penguin Rookery.

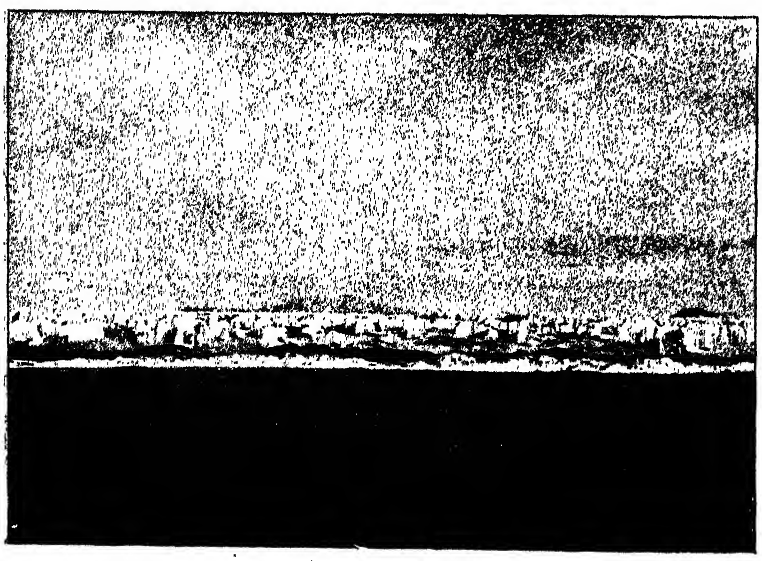

FIG. 3.—Pinnacled ice floating in McMurdo Bay.

Perhaps the most significant point in Mr. Hodgson's report is that, contrary to expectation, it was found that outdoor biological work could be carried on all the year round, "and that even with comfort." As a result, a continuous daily routine left no time for examining the material collected. Everything goes to show that animal life is very abundant in the southern seas, and a predominant feature is the enormous quantity of sponges. One organism, regarded as a Nemertine, though suspected to be something else, appeared when it arrived frozen at the ship to be "close on 20 feet long, of a light brown colour, and about the diameter of an ordinary boot-lace."

In summarising the observations on the sea ice, Captain Colbeck has "no hesitation in saying that the pack should be entered between long. 178° and 180° E., as early in December as possible."

THE STATE AND HIGHER EDUCATION.

MR. CHAMBERLAIN, in moving a vote of thanks to the Lord Chancellor—who as Warden of the University of Birmingham gave an address in Birmingham on May 13—delivered a speech emphasising the importance to the nation of higher scientific education. During his remarks Mr. Chamberlain directed attention to the fact that the University of

Birmingham is indebted to the local authority for an income of 6000*l.* a year, and referred regretfully to the circumstance that the neighbouring local authorities have not contributed very largely to the funds of the university. It must be admitted that the contribution of the city of Birmingham to its university is a handsome tribute to the value attached by the local authority to university instruction, and we join with the Chancellor of the university in hoping that suitable sums of money will be devoted in the near future by local authorities in adjoining areas to the purposes of higher education in the Midlands.

It is, however, to be regretted that Mr. Chamberlain made no reference on this occasion to the important principle—a principle he has conceded already more than once—that higher education, especially in science, is primarily a national charge. As was pointed out in the issue of NATURE for March 16, the present State grant to the University of Birmingham is 4500*l.*, an amount which compares unfavourably with the sum voted by the local city authority. Presiding at the annual meeting of the court of governors of the university on February 6 of this year, Mr. Chamberlain remarked:—

"I may say in passing that the liberality of, the local contribution is a ground for the claim which we make for some further State support. It is something that we have found that the Government are becoming alive to our needs and to our deserts, and that they have been able to double the sum previously given for university education. But we may bear in mind at the same time that the present Chancellor of the Exchequer has promised to double it again in his next Budget, and, therefore, I anticipate that from that source we shall receive a very considerable addition. I do not at all accept it as in any way a satisfaction of our demands, because it is my conviction that public opinion will soon insist upon larger sums being devoted to this purpose. When I think that we are spending thirteen millions a year at least on primary education I say the sum now given for the purpose of the highest education, the most profitable of all the investments we can make in that direction, is altogether inadequate."

If it were necessary many similar quotations could be made from Mr. Chamberlain's speeches, for he has always maintained enthusiastically the value of higher education, and recognised, at least in theory, the duty of the State to provide for it adequate financial assistance. It is noteworthy, indeed, that on the part of our leading statesmen there is an almost complete unanimity of opinion as to the paramount importance of higher scientific training for the citizens of a nation which expects to occupy a foremost place in the industrial and commercial pursuits of the world. The Lord Chancellor said in speaking to the undergraduates at Birmingham on Saturday last, that in his judicial capacity he has noticed that "the number of patents invented in Germany and brought over to England is very large indeed; the German Government has contemplated the improvement of its national resources by physical, chemical, and other scientific research, and has established places for physical investigation." Lord Halsbury might also have pointed out the amount of State aid to universities afforded in Germany. The yearly sum, found chiefly by the State, for the upkeep of the University of Berlin is 130,000*l.*, and six other universities each receive from the same source annual sums varying from 56,000*l.* to 37,000*l.*

It will be remembered that Sir Norman Lockyer said in his address in 1903, as president of the British Association, that the State does really concede the principle that higher education should be a national responsibility, by its contribution to our universities and colleges. Since that address was delivered the grant to university colleges has been increased, and it may now be said that the Treasury provides for higher education of the whole country something like the amount that is given by the State to the University of Berlin alone.

But in face of the fact that we have the concession by the Government of the principle we have maintained consistently in these columns, that university education, of the modern kind at least, should be provided by the State; and that our statesmen profess to appreciate the value of higher scientific study so far as our national welfare is concerned, and to trace to their colleges and laboratories for research the success of other nations competing with us in the struggle for national existence; no serious and statesmanlike action is taken by our Government to place our system of higher education upon a broad and generous foundation. Despite years of earnest advocacy by men of science, and repeated object lessons abroad of the advantages which early follow national sacrifices on behalf of education, little progress is made by us in the direction of supplying means to provide trained intelligences to perform the work of the country in the world's markets and manufactories. Yet, unless something in the direction adumbrated is done, knowing the earnest work which is being accomplished elsewhere, this country must, so far as industrial and economic prosperity are concerned, expect soon to take a third or fourth place in the competition of the nations.

A statesman imbued with the modern spirit, aware of present-day tendencies, possessed of the power of persuasion and clear exposition, would have little difficulty—if he really desired the best interests of the nation—in carrying the country with him by insisting that an adequate provision of higher education for those who will manage and control its industrial activities must be made a national charge.

MEETING OF THE BRITISH ASSOCIATION IN SOUTH AFRICA.

THE seventy-fifth meeting of the British Association, to be held in South Africa, under the presidency of Prof. G. H. Darwin, in August, promises to be of an unusually interesting character. Though on two previous occasions the association has met in the "British Dominions beyond the Seas," this is the first on which it will hold its annual meeting in the southern hemisphere and in a part of the British Empire so remote from its headquarters.

As early as the year 1900, the possibility of holding such a meeting was discussed by the council of the British Association in consultation with Sir David Gill, who, however, pointed out that the local circumstances were at that time unfavourable. Two years later, however, Sir David Gill informed the association that he was empowered to transmit an invitation to visit South Africa in 1905 on behalf of the various Governments, municipal, scientific, and commercial bodies in South Africa. Arrangements have now so far advanced as to enable us to give a preliminary account of the general features of the meeting and its probable character.

The invitation was issued on behalf of the above-mentioned bodies, and substantial financial assistance has been rendered by the South African Governments. The various centres to be visited are also making extensive progress, both financially and by way of private hospitality, to render the arrangements workable and adequate.

A central organising committee, under the chairmanship of Sir David Gill, has been formed to see to the general arrangements and coordination of the

work of the different centres to be visited by the association, and by means of correspondence, circulars, &c., to keep them in touch with each other and with the executive in England.

The centres, which are seven in number, are as follows:—Cape Town, Durban, Pietermaritzburg, Johannesburg, Bloemfontein, Kimberley, and Bulawayo. Influential local committees have been formed at all these places, the municipal authorities of which have taken a prominent part both in making general arrangements and in affording financial support. Subcommittees for finance, publications, excursions, and hospitality have been formed at the two chief centres (Cape Town and Johannesburg), and are now engaged in the respective parts of the work allotted to them. At the other centres where a stay of only a day or two is contemplated, special committees have also been formed. Details are as yet uncertain, but the following may be mentioned, though some of them are subject to slight revision.

The officers of the association and invited guests to the number of 200, along with ordinary members, will arrive by the *Saxon* at Cape Town on August 15, though a number have already booked their passage by steamers arriving at an earlier date. The presidential address will be delivered on the evening of the same day in the large new Town Hall, which has been placed at the disposal of the British Association by the municipal authorities of Cape Town, not only for this purpose, but also for the accommodation of the various sections should it prove suitable.

The sections will meet for the purpose of reading papers and for discussion on Wednesday, Thursday, and Friday, August 16, 17, and 18. The afternoons of these days will be partly devoted to excursions to places of interest, such as Table Mountain, Hout Bay, Simons Town, and Royal Observatory. The whole of Saturday, August 19, will be devoted to excursions.

The evenings will probably be devoted to a reception by the Mayor, and two lectures, one by Prof. Poulton on Burchell's work in South Africa, and another by Mr. C. V. Boys on physics.

On Saturday night, August 19, visitors will leave by a special steamer for Durban. In Natal an influential general committee has been formed by the Government, with local committees at Durban, Pietermaritzburg, and Ladysmith. On the evening of August 20 a lecture will be delivered at Durban and another on August 24 at Pietermaritzburg. As the reading of papers, discussions, receptions, &c., in Cape Colony will fully occupy all the time of the visitors, it is intended to afford as much facility as possible for independent action on the part of visitors in Natal, and special arrangements will be made by the Natal committee for visiting the battlefields and other places of interest.

The sectional work will be again resumed on arrival of the party at Johannesburg on Monday, August 28. There, as at Cape Town, a large and influential local committee has been formed, with subcommittees for finance, hospitality, publication, and excursions. The first-named subcommittee has already met with a ready response, both from the municipal authorities and from private sources, and the other committees are in capable hands. While the natural facilities for excursions to be found near the Cape peninsula are not to be met with here, the interest of the mining operations and gold extracting processes will be an adequate compensation, and a Friday's visit to Pretoria will be of special interest.

The proceedings will be begun at Johannesburg on Monday evening, August 28, and the presidential address there will be delivered on the Wednesday evening. In addition to sectional papers and discussions, there will be two lectures delivered at Johannesburg, one on distribution of power by Prof. Ayrton, another on steel as an igneous rock by Prof. Arnold, and one at Pretoria by Prof. Porter on mining.

Bloemfontein will be visited on Saturday, September 2. There also an influential local committee has been formed, and preparations are being made for the reception of visitors. A lecture will be delivered there on the Saturday night by Mr. A. R. Hinks on an astronomical subject.

At Kimberley, which will be reached on Tuesday, September 5, a large local committee has been formed, with subcommittees for special objects. Two lectures will probably be delivered here, one on a zoological subject by Mr. A. E. Shipley, and one on diamonds by Sir William Crookes. The De Beers Company has naturally taken a prominent part in the preparations, and will probably make this visit one of the most interesting.

Through the kindness of the Chartered Company a limited number of members of the British Association will be enabled to proceed from there to the Zambezi, where the Victoria Falls will be visited, and facilities will be afforded for the visit of a select party of specialists to the ancient ruins of Zimbabwe. A special committee at Bulawayo has been formed to make preparations there for the visit.

Special attention will be directed to certain interesting problems connected with the geological formation at the Victoria Falls, and Mr. G. W. Lamplugh, who will go out in advance to study this subject, will probably be able to give the results of his observations in an afternoon address to Section C.

Though this meeting of the association will be characterised by the number and variety of the places visited, a special feature will be the study of local scientific problems and discussions of a general nature such as fossil reptiles, Antarctica, &c. With this in view the South African Association for the Advancement of Science, with the support of the various Governments, is preparing a handbook, which will be a general review of the various branches of scientific activity in South Africa, the articles being contributed by actual workers in these subjects in the country. The book is now in an advanced stage of preparation, and a copy will be presented to each member of the association before leaving England.

SIR BERNHARD SAMUELSON, P.C., BART., F.R.S.

SIR BERNHARD SAMUELSON, F.R.S., who died on May 10 in his eighty-fifth year, will be remembered as one of the pioneers of the Cleveland iron trade, and a strenuous advocate of technical education. He exerted a great and formative influence upon an industry which owes its progress largely to the application of scientific methods, and the extension of facilities for technical education is largely due to his efforts.

Sir Bernhard Samuelson was born on November 22, 1820, and began in 1853 the business which speedily made the Cleveland district the greatest iron-producing centre in the world. Blast furnaces were erected near Middlesbrough, and in 1872–1880 collieries and ironstone mines were added. Not content with making pig-iron, the manufacture of finished iron was undertaken on an extensive scale, and no less than 25,000*l*. were spent in preliminary experiments in steel-making. The Britannia Ironworks at Middlesbrough, covering an area of twenty acres, have grown out of this enterprise.

He was the author of several reports on technical subjects to the House of Commons, including one on technical education of artisans at home and abroad.

This report was undertaken by Sir Bernhard Samuelson in 1867 at the request of the vice-president of the Committee of Council, and for the purpose of obtaining particulars he visited the principal manufacturing centres of Great Britain and the Continent. The report was published as a Parliamentary paper, and the *Times* records that it was for years referred to in all debates on technical education. He followed up this report by a Parliamentary inquiry into the education of the workmen of our manufactories in 1868, and was chairman of the committee, the report of which was adopted by the House of Commons. He was a member of the Duke of Devonshire's Royal Commission on Scientific Instruction, which issued a valuable report, and also of the Royal Commission on Elementary Education, presided over by Viscount Cross.

Sir Bernhard Samuelson was appointed chairman of the Royal Commission on Technical Instruction, the labours of which extended over the years 1882, 1883, and 1884, and embraced an examination into the systems in use in all parts of the United Kingdom and a great portion of the Continent of Europe. The exhaustive report of the Commission has become the standard authority upon the questions with which it deals. In 1888 he was appointed a member of the Parliamentary Committee for inquiring into the working of the Education Acts.

For his scientific work, Sir Bernhard Samuelson was elected a Fellow of the Royal Society in 1881, and for his many public services he was created a baronet in 1884, and was afterwards made a Privy Councillor. He was a member of the Institutions of Civil and Mechanical Engineers, and was the recipient, in 1871, of the Telford gold medal for a paper on improvements in iron manufactures. He was a member of the council of the Iron and Steel Institute, of which he occupied the presidential chair for two years. At the annual meeting of the institute held last week, the following resolution was unanimously adopted:—

"The council have received with the deepest regret the intimation of the death of their esteemed colleague the Right Hon. Sir Bernhard Samuelson, Bart., past-president, P.C., and one of the founders of the institute, and they desire to convey to Lady Samuelson and his family an expression of sincere sympathy in their bereavement. The council feel that it would be difficult to over-rate the services that Sir Bernhard rendered to the Iron and Steel Institute in the promotion of the objects for which it was formed, and they will ever remember with gratitude his constant readiness to devote his time and energies to the advancement of those objects."

DR. OTTO VON STRUVE.

THE announcement of the death of Dr. Otto von Struve does more than awaken a profound regret. His name recalls a period of past history, and summons up before us the memory of times when astronomy occupied a different position from that it assumes today, when it had fewer objects of interest wherewith to attract, and offered fewer problems for solution. Fifty-five years have gone since Otto von Struve received at the hands of the late Astronomer Royal the medal of the Royal Astronomical Society for his paper on precession and solar motion, and sixty-five since the paper was published. Seeing that Struve was born in 1819, he early came into prominence as an astronomer, and the value attached to the results and the confidence inspired by the paper are not a little remarkable, for there were some very obvious objections which might have been taken to the conclusions stated, or at least it appears so when viewed from a later standpoint. Accompanying the paper was also a discussion of the amount and direction of the solar motion. Only four years had elapsed since Argelander had published his paper assigning with some precision the place of the solar apex, and thus perhaps settling a doubt which had long divided astronomical thought. Prevost and Klugel had taken one side of the question, and Burckhardt and Lindenau led the party who were unwilling to accept the evidence. Men's minds were certainly divided as to the possibility of detecting the sun's motion, and Struve's paper came at a fortunate moment and strengthened the evidence produced by Argelander, for, based on very different material, Struve's position scarcely differed two degrees from that assigned by the Abo astronomer. Also, Struve was fairly fortunate in fixing the annual amount of the solar motion at about twice that of the radius of the earth's orbit. Later investigations have shown that a greater velocity is probable, but he was certainly correct in asserting that the linear motion of the sun appeared to be less than that of stars in general.

But it was in the domain of double stars that Otto von Struve won his reputation, and it was in this direction that he exhibited untiring industry. His father at Dorpat, and later at Pulkova, had not only devoted himself with great energy to this branch of astronomy, but had introduced a degree of accuracy into the observations that up to his time had been wanting. Otto von Struve, anxious to uphold the family reputation, was as diligent to detect these objects and as accurate in his observations as was his father before him, though he laboured under some peculiar difficulty as an observer, and was obliged to remove a systematic error which affected his observations by introducing a correction depending upon the distance of the component stars—a correction investigated with great care by means of artificial double stars.

From 1861, on the failing health of his father, Otto von Struve became the director of the Imperial Observatory at Pulkova, and in every department maintained the reputation for accuracy the observatory had won. In meridian places of stars, in cometary observations, in geodesy, in spectroscopy, the activity and efficiency of the institution have been everywhere acknowledged. In expeditions, whether for the transit of Venus or for eclipse work, the observatory has displayed its zeal and its desire to cooperate with similar work carried on elsewhere. Instruments have been renewed as needed, and the erection of the 30-inch refractor testifies to the determination to keep the observatory on a level with those best equipped. Under the care of the late director, splendid laboratories have arisen devoted to spectroscopic inquiries, and it is not too much to say that his direction of a world-famous observatory has been of a most enlightened and beneficent character. The recipient of many honours, he retired from the observatory in 1893 to enjoy the repose to which he was so well entitled amid the society of his many friends.

NOTES.

THE Croonian lecture of the Royal Society will be delivered by Mr. W. B. Hardy, F.R.S., on Thursday next, May 25, on "The Globulins."

BY the creation of the Committee of Defence, the functions and views of which were described by Mr. Balfour in the House of Commons on Thursday last, an expert advisory body has been introduced into the councils of the Government. In the discussion which followed the speech of the Prime Minister, Mr. Haldane remarked that millions of money uselessly expended would have been saved to the

country if such a committee had existed years ago. The idea underlying the formation of the committee is that for the handling of great national problems the Government must have expert assistance on a scale departmental inquiry cannot supply. Mr. Haldane suggested that it would be to the advantage of the nation if the principle of consultative committees were applied to the scientific organisation of the whole of our executive Government. "We shall never get the best service for the State until we cease to assign it merely to departments, until we can find some body to which it can be assigned that will be working under the head of the State himself. The work of the Committee of Defence illustrates the application of a new principle which will be a very familiar one before the country is much older."

THE Jacksonian prize of the Royal College of Surgeons of England has been presented to Mr. Herbert J. Paterson.

THE Elisha Kent Kane medal of the Geographical Society of Philadelphia has been awarded to Prof. William B. Scott, of Princeton University.

THE seventy-seventh annual meeting of the Society of German Naturalists and Physicians will be held this year at Meran on September 24–30.

THE Prince of Wales, as honorary president of the Royal Statistical Society, has consented to attend the opening meeting of the tenth session of the International Statistical Institute, which is to be held this summer in London.

THE Hanbury gold medal of the Pharmaceutical Society has this year been awarded to Prof. Ernst Schmidt, professor of pharmaceutical chemistry to the University of Marburg. This medal is awarded biennially for high excellence in the prosecution or promotion of original research in the chemistry and natural history of drugs, and Prof. Schmidt is the thirteenth man of science to whom the medal has been awarded. He is the first to receive, with the medal, the sum of 50*l*., which is presented to the medallist by Sir Thomas Hanbury, K.C.V.O.

WE have been requested by the council of the Society of Arts to give publicity to the following resolution passed at a meeting held on May 8:—"In view of the feeling which appears to have been aroused amongst some of the proprietors of the London Institution with regard to the proposed amalgamation with the Society of Arts, and the consequent probable difficulties of effecting a harmonious fusion of the two corporations into a single institution, the council of the Society of Arts have decided not to take any further action in the matter, and hereby discharge the committee which, at the instance of the board of managers of the London Institution, they appointed to consider the scheme for amalgamation."

THE programme has been issued of the optical convention to be held at the Northampton Institute, Clerkenwell, E.C., from May 30 to June 3, under the presidency of Dr. R. T. Glazebrook, F.R.S., director of the National Physical Laboratory. The list of papers to be read and discussed includes many of great scientific interest and practical value. Among the subjects and authors we notice:—the spectroscope in astronomy, Mr. H. F. Newall, F.R.S.; spectroscopic optics, Prof. Schuster; polishing of glass surfaces, Lord Rayleigh; parallel plate micrometer, Prof. Poynting; early history of telephotography, Major-General Waterhouse; tri-colour photography, Mr. A. J. Bull; and some directions of progress in optical glass, Mr. W. Rosenhain. The opening ceremony, presidential address, and conversazione will be held on Tuesday, May 30. A special lecture will be given by Prof. S. P. Thompson on "The Polarisation of Light by Nicol Prisms and their Modern Equivalents" on Thursday, June 1.

ON May 20 Dr. J. G. Frazer will deliver at the Royal Institution the first of two lectures on "The Evolution of the Kingship in Early Society," and on Thursday, May 25, Prof. J. A. Fleming will deliver the first of three lectures on "Electromagnetic Waves." These are the Tyndall lectures. On Saturday, June 3, Mr. A. H. Savage Landor will begin a course of two lectures on "Exploration in the Philippines." The Friday evening discourse on May 26 will be delivered by Prof. J. W. Brühl on "The Development of Spectrochemistry," on June 2 by Mr. George Henschel on "Personal Recollections of Johannes Brahms," and on June 9 by Sir William H. White on "Submarine Navigation."

THE *Times* announces the death of Lieut.-Colonel L. H. L. Irby at sixty-nine years of age. Throughout his life Colonel Irby took an intense interest in all branches of natural history, ornithology being his favourite subject. In 1875 he published a work on the "Ornithology of the Straits of Gibraltar" (south-west Andalucia and northern Morocco), a second edition of which appeared in 1894; and in 1887 appeared his "Key List of British Birds," which has proved to be of great utility to all lovers of birds. He was for many years a member of the council of the Zoological Society. He assisted in the formation of the life groups at the British Museum (Natural History), and some of the most remarkable of the cases of British birds there bear his name.

THE deaths are announced of M. Fernet, general honorary inspector of public instruction, and Prof. Victor René Muller, of Le Puy, both physicists.

OF the many valuable instruments bequeathed to the French Physical Society by the late M. Félix Worms de Romilly, the most interesting is the telescope bearing on the glass of its mirror the signature of M. Foucault. An account of this historic instrument is given by M. Cotton in the Bulletin of the French Physical Society (No. 226). The mirror has a diameter of 15·2 cm. and a focal length of 68 cm., giving a numerical aperture of about $f/4{\cdot}5$. The resolving power is 200,000, giving an angular separation of 1″. This is the only instrument constructed by Foucault with such a large aperture, and it is to be placed in the Paris Observatory after being re-silvered and adjusted by M. Cotton.

A BANQUET in aid of the funds of the London School of Tropical Medicine took place at the Hotel Cecil on May 10. Mr. Chamberlain, who presided, in proposing "The London School of Tropical Medicine," said he could not conceive of any subject of scientific research and philanthropic enterprise which was more interesting than tropical diseases, and it was a duty which we owed to the Empire, a duty which had increased in recent years with the continual extension of our territory. He thought we owed first to Sir Patrick Manson the idea of a tropical school. Almost abreast of him, if not before, came the promoters of the Liverpool School. There was room for all in this work, and they congratulated the Liverpool School on the success it had achieved. There was only one thing he envied them, and that was the liberality and energy of their citizens. He wished that in every other institution they could have a man as energetic, as devoted as Sir Alfred Jones. The London School now had accommodation for 40 students, and since its foundation six years ago 503

students had passed through it. They had to thank Sir John Craggs for founding a scholarship and prize, and Mr. Bomanji Petit, a Parsee gentleman, for a contribution of 700*l*. The committee now asked for the sum of 100,000*l*. for endowment, which amount was a mere drop in the bucket in comparison with the Liverpool subscriptions. The other speakers were Sir P. Manson, Mr. Alfred Lyttelton, M.P., Lord Strathcona, and the Duke of Marlborough, and among the 400 guests were Lord Rothschild, Sir Douglas Powell, Sir T. Barlow, the Hon. Sydney Holland, Sir Alfred Jones, Prof. Blanchard, Prof. Dunstan, the Hon. John Cockburn, Major Ronald Ross, Sir A. W. Rücker, Mr. Jonathan Hutchinson, Sir W. S. Church, and Mr. Watson Cheyne. Subscriptions and donations to the amount of more than 10,000*l*. were received.

THE visit of the French doctors to London last summer was so successful that a return visit of their British *confrères* to Paris was arranged, and the party arrived on May 10. The proceedings commenced with an evening reception at the Sorbonne. M. Ziard, president of the university council, and Dr. Bouchard, Sir William Broadbent, chairman of the London executive committee, Prof. Clifford Allbutt, of Cambridge, and Dr. George Ogilvie, senior physician to the French Hospital, London, exchanged mutually congratulatory speeches. The extensive and beautiful university buildings were thrown open, and were much admired. On Saturday the visitors attended a reception at the Pasteur Institute. Dr. Roux, the director of the establishment, welcomed the visitors in a short speech, in which he recalled the great services rendered to Pasteur by Lister. In the crypt of the institute, the dean of the medical faculty of the University of London, Dr. J. K. Fowler, laid a wreath upon Pasteur's tomb bearing the following inscription:—"A ce grand Pasteur, le bienfaiteur de la race humaine." In the course of his address Dr. Fowler is reported by the Paris correspondent of the *Times* to have said:—"We desire to offer a tribute of our profound admiration for the great Frenchman whose noble life and example will ever be an inspiration to those who, like him, are devoted to the cause of science. The discoveries of Pasteur alone would suffice to give the nineteenth century a preeminent place in the annals of science. Science knows no frontiers; it unites in a common brotherhood all who devote their lives to its service. Those who humbly follow, no matter at how great a distance, in the footsteps of Pasteur help to unite the peoples of the world. We are convinced that the friendship between France and Great Britain will ever continue to increase in cordiality, and that the two nations will work in accord for the advancement of science and will only strive for the attainment of one noble aim, the peace of the world." On Saturday evening a banquet was held under the presidency of Prof. Bouchard, who, after reading a congratulatory telegram from M. Loubet, announced that he had received from the President of the Republic the mission to bestow upon Sir William Broadbent the insignia of the rank of Commander of the Legion of Honour.

A REUTER telegram from Berlin reports that in the course of excavations in the neighbourhood of Breslau 400 graves and 150 prehistoric dwelling places were brought to light. The oldest of the graves contained bones dating from a period previous to the Bronze age, and in another grave near by were found urns showing that they had contained bodies interred five centuries later. The excavators have been able to trace the site of a village of the Bronze age. About a dozen huts are clearly recognisable. A whole collection of spinning and weaving appliances has also been dug up.

PROF. F. A. FOREL, writing from Morges, directs our attention to an earthquake which occurred on April 29 last. The centre of the seismic disturbance appears to have been in the neighbourhood of Martigny, Argentière, and Chamonix, and its intensity at the centre was viii. on the Rossi-Forel scale. The time of the principal shock was April 29, 1h. 45m. Greenwich time. The seismic area was of 250 kilometres radius, and included 200,000 square kilometres, comprising Valais, western, central, and eastern Switzerland, upper Italy, and western France. Further shocks were experienced at Martigny and Chamonix on May 1 at 19h. 22m. and 21h. 53m.; on May 2 the movements were very slight, and on May 6 a shock occurred at 4h. 45m.

REUTER'S Agency is informed that Mr. W. Champ, the leader of the expedition which is being dispatched to Franz Josef Land to rescue the twenty-six American explorers who have been in the Arctic for the past two winters with their ship, the *America*, left England on Saturday for Bergen. He was accompanied to Norway by Dr. Oliver L. Fassig, who has been dispatched by the United States Weather Bureau and the National Geographic Society of Washington to be their representative on the second relief ship, which will be dispatched from Norway to the east coast of Greenland. The main relief expedition, of which Mr. Champ is in command, will leave Tromsö in about a fortnight on board the *Terra Nova*, and will make straight for Capé Flora, Franz Josef Land, where it is expected that records will be found, and probably also some of the explorers who, under Mr. Fiala, the leader of the expedition, have been cut off from all communication with the outside world since July, 1903.

MESSRS. FRIEDLÄNDER AND SON, of Berlin, have sent us a copy of a catalogue of books and pamphlets dealing with the anatomy and physiology of invertebrates.

To the April issue of our Scandinavian namesake, *Naturen*, Dr. H. Magnus contributes the final instalment of his account of South Polar expeditions.

THE birds of the Isle of Pines (about 60 miles south of Cuba), by Messrs. Bangs and Zappey, and the fifth instalment of Dr. B. M. Davis's studies on the plant-cell, constitute the contents of the April number of the *American Naturalist*.

No. 3 of the "Cold Spring Harbour Monographs," by Miss Smallwood, is devoted to the Salt-Marsh amphipod *Orchestia palustris*, a species showing more decidedly terrestrial habits than its immediate relatives, and therefore, presumably, a more specialised type.

THE two plates issued in No. 3 of vol. xxv. of *Notes from the Leyden Museum* illustrate papers on molluscs. In the first of these Mr. M. M. Schepman describes a new species of Trochus from the Indian Ocean, and the adult condition of *Bathybembix aeola*, a Japanese form originally described from an immature specimen collected during the voyage of the *Challenger*. In the second Dr. H. F. Nierstrasz reviews the collection of chitons in the Leyden Museum, describing new species.

THE hereditary relations of plants to the diurnal and seasonal periods of their environment form the subject of an instructive article by Dr. R. Semon in *Biologisches Centralblatt* of April 15. In the same issue Dr. Wasmann

continues the account of his researches into the development of slavery among ants. It is interesting to note that the various local races of the widely distributed *Polyergus rufescens* respectively possess different types of slave-ants, which are for the most part subspecies of *Formica fusca*, although in one case the enslaved species is *F. nitidiventris*.

In connection with the latter part of the preceding paragraph, it may be mentioned that the April number of *Himmel und Erde* (Berlin) contains an illustrated popular account of the "flower-gardens" made by ants in the crowns of trees in Amazonia and Peru, as discovered and described by Mr. E. Ule. These "gardens," or perhaps we might rather say "baskets," are shown in various stages of growth, from the time when the plants are just budding until the long slender leaves of *Streptocalyx angustifolius*, which appears to be the favourite species, are fully developed. All the plants cultivated appear to have very minute seeds, or spores, which seem to be sown by the ants in their nests.

Mr. L. M. Lambe has sent us a copy of a paper by himself from the *Ottawa Naturalist* (vol. xix., part i.) on a large new species of sponge of the genus Esperella from the Pacific coast of Canada. We have also received a pamphlet on the life-history of the pear-midge (*Diplosis pyrivora*), by Mr. W. E. Collinge, published by Cornish Brothers, Ltd., Birmingham, as No. 2 of "Reports on Economic Zoology." It contains good figures of the various stages of the development of this pernicious insect, showing the manner in which it destroys young pears.

Among other articles in *Naturwissenschaftliche Wochenschrift* for April 30 is one by Dr. J. Meisenheimer summarising the results of recent investigations with regard to the origin and formation of pearls. Several illustrations indicate the positions in which pearls are usually found in shell-fish, while others show their internal structure, and others, again, the parasites usually constituting the nucleus. The researches of Mr. H. L. Jameson and of Messrs. Herdman and Hornell form the basis of a large portion of the paper.

It has been repeatedly noticed that when a pair of rooks attempt to build apart from the rest in a tree previously unoccupied, the other members of the colony not unfrequently set to work to destroy the nest. An event of this nature is recorded in the *Craven Herald* of April 28 as having taken place in the churchyard of Christ Church, Skipton. In this instance a pair of rooks had built in a tree overhanging Cross Street, and the female was incubating her eggs. While thus engaged she was attacked by the other rooks, who pecked her to death, throwing the body, together with the broken eggs and the ruined nest, to the ground. The attack was witnessed by many persons.

According to Mr. E. E. Green, in the March number of *Spolia Zeylanica*, the elephant-mosquito (*Toxorhynchites immisericors*) differs from Anopheles and many other members of the gnat family in that the larva is carnivorous. This carnivorous habit was suggested by the structure of the head of the larva, and observation showed that these larvæ prey upon one another as well as upon those of other gnats. In fact, but a single survivor was eventually left when a number of larvæ were placed in the same receptacle. In a second article Mr. A. J. Chalmers records the species of Anophelinæ found in Ceylon, while in a third Mr. H. Schoutenden contributes notes on Ceylonese aphides, with descriptions of new forms. Considerable interest attaches to a note by J. Hagenbeck in the same issue on an incubating python which safely brought off a number of young snakes.

In the *Zeitschrift für wissenschaftliche Zoologie*, vol. lxxix., part i., Mr. O. Schroeder, of Heidelberg, discusses the abdominal sense-organ, or so-called abdominal eye, of the palolo worm (*Eunice viridis*) of Samoa. This organ differs so widely from all definitely known types of eyes that it is difficult to find a basis of comparison. Indeed, whether it is an organ for the perception of light at all is extremely doubtful. The reasons that it has been regarded as such are the presence of nerve-cells, pigment, and a lens; but similar pigment is found in other parts of the creature's body, while the so-called lens would not come under the optician's definition of such an instrument. Pigment and lens-like structures are not unfrequently met with in luminous organs, but the so-called eye of the palolo worm certainly does not come under this category. In no other annelid has a similar organ been detected. The other articles in the same issue include one by Mr. P. Heinemann on the development of the mesoderm and the structure of the tail in the ascidian larva; a second, by Dr. M. Lass, on the histological anatomy of the female dog-flea; and a third, by Mr. A. Rufini, on the existence of an undescribed sheath in the terminal tract of human sensor nerves.

Prof. W. B. Benham, writing from the Otago University Museum, Dunedin, comments upon Dr. Alex. Hill's letter in our issue of February 2 on "Can Birds Smell?" Prof. Benham says that several points concerning the structure and habits of the kiwi suggest that its sense of smell is possibly highly developed. The nostrils, instead of being at the base of the beak, are at the extreme tip and on the under surface. The olfactory sacs, with their complex of turbinals, extend so far back as to project into the orbits, the eyes being separated by them instead of by a thin bony interorbital septum. The eyes of the bird are small and inefficient, notwithstanding its nocturnal habits, and observers state that the kiwi seeks its food by its sense of smell or hearing. In searching for food, the bird thrusts its beak into moss, piles of leaves, or into holes in the ground, and assumes an attitude suggestive of trying to obtain evidence of the presence of food either by smell or by listening for the sound of movements made by a worm in its burrow. These statements suggest the probability of a well developed sense of smell by the kiwi, and Prof. Benham hopes to have experiments carried out on the apteryx, oxydromus, and stringops in order to obtain evidence upon the matter.

The *Century Magazine* for May contains articles by Mr. Brush on the evolution of the arc electric light, by Mr. Holland on the recently discovered white bear of north-western British Columbia, and by Dr. McGee on the Japanese Army medical service. In the last named the organisation is described, particularly the arrangements in force for treating and transporting the large number of wounded from the seat of war, and the sanitary arrangements whereby typhoid and dysentery, the great scourges of armies in the field, are hardly known.

The April number of the *Bulletin of the Trinidad Botanical Department* contains articles on the phosphoric acid requirement of cacao plants, and on coffee curing for the small settler. The record of the visits paid by the two agricultural instructors to different districts and schools shows that their services are highly appreciated throughout the island.

THE fact is not generally known that species of the cycad Zamia can be artificially multiplied by cuttings. The subject of regeneration in Zamia is treated by Dr. J. M. Coulter and Mr. M. A. Chrysler in the *Botanical Gazette* (December, 1904). As a rule, new growth proceeds from meristematic tissue of the cork, but an instance is mentioned in which a portion consisting only of cortex gave rise to new shoots and root.

THE Department of Agriculture at Nairobi has instituted a series of leaflets which should be most useful to settlers in British East Africa. The first, issued in January, gives the native names in different dialects for the principal crops. A second provides some useful hints for cotton cultivators. Egyptian seed is recommended in preference to Sea Island or upland American, because, so far as experience goes, it has produced heavier crops, and also because it has been less affected by unfavourable conditions of the weather.

WE have received vol. xxvii. of *Aus dem Archiv der deutschen Seewarte,* for the year 1904. This valuable work, like its predecessors, contains some important discussions of meteorological and kindred subjects by well known men of science. One by Dr. W. J. van Bebber, entitled "Barometer and Weather," is of especial interest to meteorologists. He discusses, with reference to Hamburg more particularly, the relations of barometrical conditions to rainfall, temperature, and weather generally for the year, seasons, and months, for a period of twenty-five years. On this subject he brings to bear the special knowledge obtained as chief for many years of the Hamburg weather forecast department.

THE Meteorological Office has issued a circular stating that it will, as before, supply forecasts of weather by telegraph to agriculturists during the coming harvest season, at the cost of telegraphy only. These forecasts are prepared each afternoon from June 1 to September 30, except Sundays; but in view of the suspension of agricultural work on that day the office will, if required, transmit special forecasts on Saturday evening, giving, in very general terms, the prospects of the weather for the ensuing forty-eight hours. In the last published annual report of the office it is stated that many of the recipients of these forecasts keep a record of the weather experienced during the time the forecasts are sent, and return them to the office for the purpose of checking the results. From this comparison it appears that about 50 per cent. of the telegrams were completely successful.

MESSRS. CARL ZEISS, of Jena, have issued a new catalogue (in English) of their photomicrographic outfit for use with ultra-violet light of wave-length 0·275 μ, in addition to several catalogues of new ordinary microscope stands. The whole of the glasses—eye-piece, objective, slips and cover glasses—are of fused quartz, and the source of light is supplied by the current of sparks of a Leyden jar between cadmium electrodes. We notice one correction—dissolving power should be resolving power.

AMSLER'S planimeter is so well known to mathematicians that there is no need to direct their attention to its usefulness. We have, however, just received a small pamphlet by Mr. William Codd (London: E. and F. N. Spon) entitled "Land Area Computation made Easy," the object of which is to show non-mathematical readers how simple is the process of computing areas from maps or plans with this instrument. Mr. Codd has also, we learn, published "land area tables" to facilitate reduction to acres, roods, and perches, thereby saving the tedious calculations which are unnecessary in countries using the metric system.

A SERIES of observations on respiration at high altitudes is described by Prof. Angelo Mosso in the *Atti dei Lincei,* xiv. (1) 6. A special feature of these observations is the effect of carbon dioxide as a remedy for mountain sickness, a property regarding which experiments performed both on human subjects and on monkeys have led to most conclusive results in Prof. Mosso's hands. It is recommended that about 8 per cent. of carbon dioxide should be added to the compressed oxygen carried for use in high balloon ascents, as pure oxygen is not in itself sufficient to remedy the effects of great barometric depressions.

IN the *Transactions of the Institution of Engineers and Shipbuilders in Scotland* (xviii., 5), Mr. John Riekie discusses the various systems of compound locomotive engines, and describes a new form with which he has experimented. In it there are two equal high-pressure cylinders and one low-pressure cylinder of about $1\frac{1}{4}$ times the volume of the combined pair. It appears to differ from the well known "Webb" compound in that the crank-rods are all connected to a single three-throw crank set at angles of 120°, instead of working on the cranks of the axles of the two different driving pairs. It requires no special starting gear.

THE *Atti* of the Lincei Academy (xiv., 4) contains the announcement of the foundation by the King of Italy of a new international institution of agricultural studies. Among the advantages likely to accrue from the establishment of such an institution, the advancement of our knowledge of the best methods of combating against plant-diseases is specially mentioned. On this latter branch of study an interesting paper occurs in the same number of the *Atti,* by Dr. Vittorio Peglion, on the pathology of *Euonymus japonica.* This shrub, so common in Italian gardens, has been for many years subject to diseases, traceable in the first place to a scale insect, and in the second to a species of Oidium described by Saccardo and Arcangeli under the name of *Oidium evonymi-japonicae,* with which the present paper deals.

FROM a copy of the *Corriere di Catania* received from the Observatory of Catania, we gather some interesting particulars of the sudden eruption of Stromboli which took place about four weeks ago. On April 16, at about 2.9 p.m., a tremendous explosion as of a big cannon was heard, and the whole of the eruptive portion was enveloped in a dense black smoke. A large number of masses about one metre in diameter, and other smaller ones, were projected to a distance of 200 metres, and rolled down the Sciara del Fuoco to the sea, raising clouds of dust in their descent. Four or five minutes later there was a fall of scoriæ, about 5 cm. in diameter, over an area 4 kilometres long and 400 metres broad running E.N.E. of the volcano, in which direction the wind was blowing. A shower of ashes followed, and a quarter of an hour later a slight shower of rain occurred. At the time of the eruption Dr. Schulze was 300 metres to the south of the eruptive cone, where he was wounded in the head and leg by falling stones, fortunately not seriously. According to him, the opening by which this explosion took place is in the centre of the six others; it is known as No. 4. A considerable panic occurred throughout the island, and many of the inhabitants declare that such an eruption has never been witnessed before.

IN the Journal of the Russian Physical and Chemical Society (1904, No. 4) we notice the following papers:—An elaborate sketch and scientific analysis of the work, in organic chemistry, of Prof. Egor Egorovitch Wagner, by

V. V. Lavroff, followed by a full bibliographical index.—Determination of the inner energy of the gas-liquid systems, by A. N. Tschoukareff, with a *résumé* in French. By sealing various liquids in steel "sparklets," capable of supporting considerable inner pressures, the author could thus bring these liquids to high temperatures, above the critical temperature, and thus determine the specific heat of these substances in the critical state.—On the theory of the singing Voltaic arc, a mathematical inquiry by S. Maysel, which brings the author to conclusions opposed to those of Duddell, Janet, and Granqvist.

Messrs. Macmillan and Bowes, Cambridge, will publish in a few days a small book on "Mendelism," by Mr. R. C. Punnett, Cambridge. The volume will give an outline of Mendel's work on heredity, and its recent developments.

In the notice of Dr. D. Murray's volumes on "Museums" in our issue of April 13 (p. 554), the reviewer referred to the list of museums in the United Kingdom given in the work as being based on one prepared by the Museums Association. Mr. E. Howarth writes to point out that the list was a reprint of one prepared by a committee of the British Association in 1887, and not by the Museums Association, which did not commence the preparation of a museums directory until 1902.

Messrs. George Bell and Sons have published the second part of the key to the "Elementary Algebra" of Messrs. W. M. Baker and A. A. Bourne.

OUR ASTRONOMICAL COLUMN.

Orbit of Comet 1905 *a*.—A graphical representation of the orbit of comet 1905 *a*, according to the elements computed by Miss Lamson, of the U.S. Naval Observatory, is given in No. 5, vol. xiii., of *Popular Astronomy*. From this it is seen that the comet, at its perihelion, passed within 12,000,000 miles of the earth, but the latter body had, about a month before, passed the point where closest proximity was possible. The comet will continue, therefore, to grow fainter, and on May 30, according to Miss Lamson's ephemeris, it will be only 0·3 as bright as when first discovered, and it was only a faint telescopic object then.

Provisional Elements for Jupiter's Sixth Satellite.—Whilst awaiting more definite information from Lick, Mr. Crommelin has computed provisional elements for Jupiter's sixth satellite from the data already available. These data are not sufficient to decide the eccentricity of the orbit, so a circular form has been assumed. Although the Lick observers have now stated definitely that the "retrograde" in their first telegram did *not* refer to the orbital motion, the observations yet made have not settled the question of direction, and Mr. Crommelin has therefore computed elements both for "direct" and "retrograde." He finds the distance from the parent planet to be about 6,200,000 miles, and a comparison of this with the observational data favours a "direct" orbital motion, although, of course, much uncertainty exists. The inclination of the satellite's to the planet's orbit is 23°·8 or 23°·9, according to whether the motion is "direct" or "retrograde," whilst the inclination of the orbit to Jupiter's equator is either 26° or 24°·7. This inclination is unusually large as compared with other satellite orbits in the solar system, and according to the reports so far received the orbit of the seventh satellite has a still larger inclination.

According to the "direct" hypothesis, the pole of the sixth satellite's orbit is only about 1°·5 from our own North Pole, so that the major axis will always point nearly due east and west. A determination of the position angle next July, when it again reaches western elongation, should decide the question of the satellite's motion. The semi-minor axis of the apparent ellipse on December 25 (W. elongation) was 4′·96, and from this it is deduced that the inclination of the orbit plane to the line of sight on that date was 5°·7 (*Monthly Notices*, vol. lxv., No. 5).

Winter Fireballs in 1905.—In No. 357 of the *Observatory* Mr. Denning summarises the accounts of fireball observations, during January and February, which have been forwarded to him. Quite an unusually large number of these objects were observed. One slow meteor seen on January 27 at 11h. 59m., and another seen on February 28d. 12h. 10m., were at least as bright as the full moon, whilst one on January 14 at 10h. 16m., which was brighter than Venus, was noted by one observer as being followed by a slight rumbling noise at an interval of $2\frac{1}{2}$ minutes. The probable radiant of this object was 119°+3°, and it travelled from a height of 60 miles to a height of 29 miles, along a path of about 55 miles, with a velocity of 15 miles per second. A meteor seen at 10h. 15m. on February 28 from a radiant at 220°+40° divided into two parts at disappearance, whilst the last named of the eighteen objects mentioned in Mr. Denning's report, seen at 9h. 10m. on March 18, swelled out and exploded three times with lightning-like flashes during its four seconds' flight.

Observations and Light-curves of Several Variable Stars.—In No. 4011 of the *Astronomische Nachrichten* Dr. L. Terkán, of the O-Gyalla Observatory, publishes the results of a series of observations, and some light-curves, of several important variable stars. The observations were made during 1904 with a Zollner photometer, and the results are compared with the various published elements of each object. The stars dealt with are S Sagittæ, T Vulpeculæ, δ Cephei, η Aquilæ, β Persei, and λ Tauri.

Observations of "D_3" in the Solar Spectrum.—In No. 4012 of the *Astronomische Nachrichten* Dr. H. Kreusler, of Berlin, records two observations in which he saw the helium line, D_3, as a dark line in the spectrum of the region about a sun-spot. The first observation was made between noon and 2 p.m. on June 12, 1904, the second on the following day, and on both days the faculæ surrounding the spot were exceptionally bright. Dr. Kreusler suggests that, as it was near a maximum epoch of solar activity when Prof. Young recorded a similar observation in 1870, this phenomenon may be a characteristic of sun-spot maxima.

Brightness of Jupiter's Satellites.—In an attempt to settle the question of the variability of Jupiter's four brightest satellites, Prof. Wendell, of Harvard, made a series of photometric comparisons of them with a polarising photometer attached to the 15-inch telescope. The satellites were compared, for brightness, among themselves, and a large number of "settings" was made in such a manner as to eliminate accidental errors. The order of brightness was always iii., i., ii., iv., and the results afford no evidence for any variability during the period over which the observations extended, viz. from J.D. 2416900 to J.D. 2416928 (Circular No. 95 of the Harvard College Observatory).

Variable Stars in the Small Magellanic Cloud.—Some time ago it was reported in these columns that Miss Leavitt had newly discovered 57 variable stars in the small Magellanic cloud. In order to provide material for a closer study of the light-curves of these objects, sixteen negatives were taken at Arequipa with the 24-inch Bruce telescope, with exposures varying from two to four hours each. When the plates arrived at Cambridge (U.S.A.) in January, Miss Leavitt was greatly surprised to find that in this same region there were hundreds of variables which had not been seen on the previous inferior plates. In Circular No. 96 of the Harvard College Observatory the number in each half-degree square of the region is given, and, including the 57 previously announced, there are 910 new variable stars in all. This means that within the limits of the clouds there is one variable to every 308 stars, whereas of the 40,000 stars in the surrounding region shown on the plates only one in 3300 is apparently a variable, although all have been examined with equal care.

During the examination of the plates it was found that a thirteenth magnitude star, the position of which for 1900·0 was R.A.=1h. 6m. 1s., dec.=−72° 45′·5, has a large proper motion amounting to +0·13s. in R.A., +0″·42 in dec., and 0″·73 in a great circle.

SANITATION IN THE TROPICS.[1]

PROF. BOYCE and Messrs. Evans and Clarke, of the Liverpool School of Tropical Medicine, recently returned from a journey to the west coast of Africa, the object of which was to study the present sanitary condition of, and anti-malarial measures practised at, Bathurst, Conakry, and Freetown, to investigate how far the teaching of Ross has there been accepted and acted upon, and if, as a consequence, the health of these communities has improved during the last four years. This report embodies the results of their observations, together with suggestions for the further development of tropical hygiene in the future.

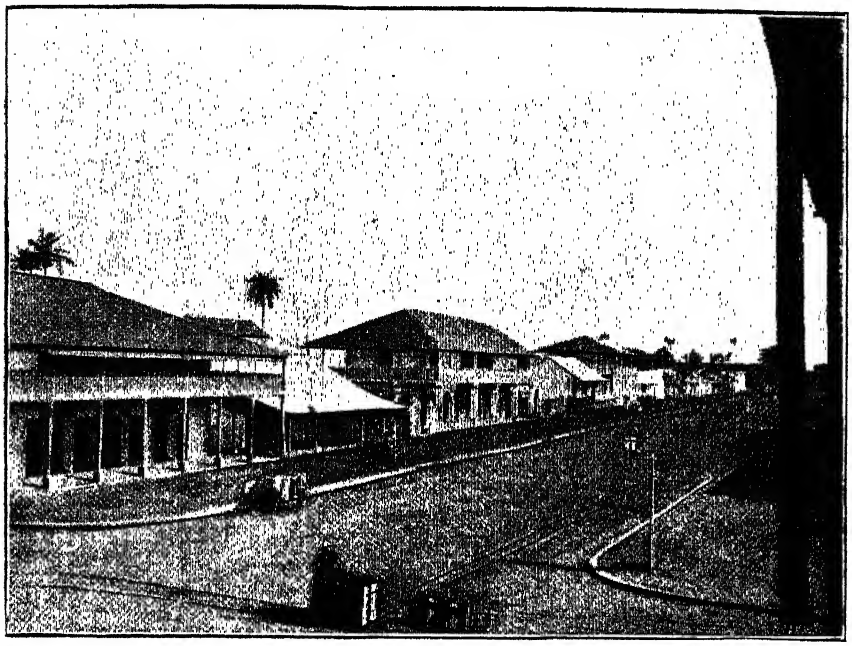

FIG. 1.—Principal Boulevard in Conakry, showing factories and Decauville rails. The main drain is under the footpath on the left.

At Bathurst sanitation is clearly of no low order, the town is well laid out, the streets are drained, and earth closets are the rule in the European quarters; but in the native compounds there are many cess-pits which tend to foul surface-wells, of which there are a number still in use, though there is a good public supply from deep wells. Anti-mosquito measures have been in force since 1902, consisting of the removal of old tins and rubbish, levelling and clearing of roads, examination of wells and water receptacles for larvæ, &c., and the more regular use of the mosquito net by Europeans. These precautions have made people think and be more careful, and the Europeans, it is stated, have been more free from malaria than formerly, but Culex mosquitoes still abound.

Conakry, in French Guinea, is a comparatively new town, well planned and laid out. There are no cess-pits of any kind, the pail system being in use, and a pure water supply is brought from watercourses 41 kilometres distant. In consequence, the private wells have fallen into disuse, but they have not been closed or filled up, and therefore serve as breeding grounds for mosquitoes. Anti-malarial measures do not seem to be carried out, mosquito nets are not made use of to any extent, and malaria is still very rife. The authors remark that (p. 20) "With model water supply under the control of the authorities, no streams, a good porous soil, and perfect sanitation mosquitoes should be got under control, and the freedom of the Europeans and of the natives from malaria guaranteed."

Freetown, in Sierra Leone, is not well laid out, and cess-pits are the rule. Of these there were 2650 in 1897, and their number has since increased, while more than 2000 of the inhabitants have no sanitary accommodation of any kind. The street drainage is still imperfect, and numerous opportunities exist for Anopheles mosquitoes to breed; but this condition of things is undergoing gradual improvement, and mosquito nets are in general use. The authors think that the health of the Europeans has in consequence improved, but evidently no striking result has yet been achieved. On the whole, we are disappointed that more definite results cannot be chronicled as the outcome of the health propaganda

FIG. 2.—A street in Freetown consisting of rock surface, in which there are innumerable pools breeding Anopheles (Rainy season).

so ably preached by the Liverpool School and its energetic staff, but obviously such success as has been attained should prove a stimulus for further effort, and not lead to any relaxation of present measures. The authors formulate a number of suggestions for the improvement of the health of the districts visited, of which the principal are:—(1) the

[1] "Report on the Sanitation and Anti-malarial Measures in Practice in Bathurst, Conakry, and Freetown." By Prof. Rubert Boyce, M.B., F.R.S., Arthur Evans, M.R.C.S., L.R.C.P., and H. Herbert Clarke, M.A., B.C. (Cantab.), Liverpool School of Tropical Medicine. Memoir xiv. (Liverpool: University Press. London: Williams and Norgate, 1905.)

instruction of newcomers in the part played by mosquitoes in conveying malaria, and in the habitual and proper use of mosquito nets; (2) the segregation of the native population away from the European quarters; (3) the total abolition of cess-pits; (4) the rational and systematic use of anti-malarial measures; (5) the public control of drinking water; and (6) the establishment of laboratories on the spot for the study of health problems. R. T. HEWLETT.

IRON AND STEEL INSTITUTE.

THE annual meeting of the Iron and Steel Institute was held at the Institution of Civil Engineers on May 11 and 12, and was very largely attended. The report of the council, read by Mr. Bennett H. Brough, the secretary, shows that the institute continues to make satisfactory progress. The membership now amounts to 2000. The proceedings began with the adoption of a resolution of regret at the death of Sir Bernhard Samuelson, Bart., P.C., F.R.S., past president, referred to elsewhere (p. 61).

After the usual routine business, the retiring president, Mr. Andrew Carnegie, inducted into the chair the president-elect, Mr. R. A. Hadfield, whose first duty was to present the Bessemer gold medal to Prof. J. O. Arnold (Sheffield).

Mr. R. A. Hadfield then delivered his presidential address. It dealt chiefly with the history of metallurgy and with those branches of the subject to which his attention had been directed, more especially with the alloys of iron with other elements. He urged the necessity for constant research. In progressive manufacture, the complexity of which increases year by year, there is, in addition to the many ordinary difficulties met with, that of the solution of new problems which constantly present themselves. This can only be done by research, which should form an actual part of industrial operations, and demands almost as much attention as is devoted to the manufacturing side. It is more than ever necessary not to rest satisfied with the knowledge of to-day, or to think that this will satisfy the needs of to-morrow. Rapid and great changes are constantly occurring in metallurgy as in other branches of scientific knowledge. The thanks of the meeting for the address were expressed by Sir E. H. Carbutt and Sir William White, K.C.B.

Mr. S. Surzycki (Czenstochowa) submitted results obtained with the continuous open-hearth steel process as carried out in fixed furnaces in Poland. The process, which has proved eminently successful, is based on the principle of the Talbot process, with the essential difference that it can be carried out in any fixed furnace of not less than 25 tons capacity. The advantages do not consist solely in the continuity of the process, but in the longer life of the furnace, the higher production and yield, the lessened fuel consumption, and the simplicity of the plant.

A very elaborate paper was read by Mr. R. A. Hadfield, the president, describing some experiments relating to the effect produced by liquid-air temperatures on the properties of iron and its alloys. About eleven hundred specimens were tested. The bars, which were prepared with great care, were submitted to various heat treatments, the exact temperatures being recorded, and then forwarded to Sir James Dewar's laboratory at the Royal Institution. The tests were carried out on a small hydraulic testing machine, to which the necessary arrangements could be readily applied for immersing the specimens in liquid air. The results showed that, with certain exceptions, the effect of low temperatures is to increase in a remarkable degree the resistance of iron and iron alloys to tensile stress, and to reduce the ductility from the highest point to practically nil. The changes take place even in the softest wrought iron. The absence or presence of carbon in ordinary carbon steel in which other special elements are not present has little influence. Subjected to Brinell's hardness ball test, a specimen of Swedish charcoal iron at normal temperature had a hardness number of 90, whereas when tested at about $-182°$ C. this increased to no less than 266, or about equal to the hardness of 0·80 per cent. carbon steel at normal temperature. This almost seems incredible when it is remembered that this iron shows by analysis 99·82 per cent. of iron, and normally has only 20 to 22 tons tenacity with 25·30 per cent. elongation. This iron becomes brittle to an extraordinary degree under the influence of the low temperature $-182°$ C., whereas nickel tested at the same low temperature has improved rather than deteriorated, not only in tenacity, which iron also does, but in ductility, in which latter quality iron entirely breaks down. If nickel, therefore, is present in an iron alloy containing but little carbon or comparatively low in that element, it acts as a preventive of brittleness, or is a very considerable modifier of that objectionable quality. This action of nickel is simply marvellous in certain of the alloy specimens, for example, in the case of an alloy of iron, carbon 1·18 per cent., nickel 24·30 per cent., and manganese 6·05 per cent. Here the ductility is extraordinary at not only ordinary but low temperatures, probably the highest known for any iron alloy, and certainly for an alloy having such tenacity as 84 tons per square inch. There is still present in this alloy 68 per cent. of iron, yet the tendency of the latter metal to wander into the paths of brittleness is not only entirely checked at the liquid air temperature—and this brittleness, as shown so clearly in this research, occurs to an extraordinary extent in pure iron cooled to $-182°$ C.—but the elongation or ductility, already so great, is considerably increased, namely, from 60 per cent. to $67\frac{1}{2}$ per cent. There is also an increase of tenacity in both cases, namely, a rise of from 10 per cent. to 38 per cent. Thus the nickel present enables the bar under this high tension and at $-182°$ C. to remain far more ductile than the very best of ductile iron of one-third the tenacity. Although the action of nickel has been specially referred to, it must not be overlooked that in this alloy there is also present 6 per cent. of manganese, which in its ordinary combination with iron, that is, with no nickel present, would confer intense brittleness upon the iron and render it more brittle than if not present. This treble combination of nickel-manganese with iron appears to reverse all the known laws of iron alloys.

Mr. J. H. Darby (Brymbo) and Mr. George Hatton (Round Oak) summarised the recent developments in the Bertrand-Thiel process of steel manufacture. This process, which was first used in Bohemia in 1894, consists in carrying out the preliminary refining in an upper open-hearth furnace, and the steel-making is completed in a secondary open-hearth furnace. The original plan of having furnaces at different levels has not proved so satisfactory as having the furnaces arranged in line with a mixer at one end. Pig iron of almost any ordinary composition may be used. At Brymbo, with a highly phosphoric pig iron, seven 20-ton charges per day have been attained, and at the Hoesch works in Dortmund ten charges per day have been regularly produced.

At the New York meeting of the Iron and Steel Institute, the paper read by Mr. James Gayley on the application of the dry air blast created quite a sensation in the iron industry. Mr. Gayley now gives, in a supplementary paper, a record of operations of the Isabella furnaces at Pittsburg from November, 1904, to March, 1905, showing that the increased iron output and the decreased coke consumption derived from the use of dry air were well maintained.

The rapid development of the gas engine of recent years has given special value to the gas escaping from the blast furnace, previously often described as waste gas. The gas leaving the blast furnace carries with it a varying amount of gritty dust, which has proved a serious obstacle to the successful operation of large gas engines. The various methods of cleaning the gas were described in the paper submitted by Mr. Axel Sahlin, who has designed a slowly revolving apparatus for the purpose.

Dr. O. Boudouard (Paris) submitted a lengthy account of experiments made to determine the fusibility of blast-furnace slags. He gave a chart enabling metallurgists to determine the fusion temperature of a given alumino-calcic silicate. The information given in this lengthy paper is of great value, inasmuch as one of the most important considerations in the satisfactory running of a blast furnace is a knowledge of the degree of fusibility of the slag.

Mr. Sidney A. Houghton contributed a note on the failure of an iron plate through fatigue. The plate was

from the boiler of a portable engine about twenty years old. Microscopic examination showed that the effect of fatigue stresses on the plate had been to form cracks commencing as a rule from irregularities on the inner surface, which cracks were due to weakness in the cleavage planes of the crystals from continual slipping, and to a less degree to some loss of adhesion between the crystals. Some of the crystals appeared to have been broken up, and the slag flaws seemed to have a restraining effect on the progress of the cracks.

Mr. B. H. Thwaite (London) directed attention to accidents due to the asphyxiation of blast-furnace workmen, and described an apparatus for the rapid detection of the presence of carbon monoxide in air.

Prof. F. Wüst and Mr. F. Wolff (Aachen) submitted a paper on the behaviour of sulphur in the blast furnace. They showed that, contrary to the generally held opinion, the sulphur in the coke does not reach the level of the tuyeres of the blast furnace without undergoing alteration, but a great portion of it is previously volatilised by the ascending gases. It is then largely absorbed from the gases by the descending charge, and in this condition arrives in front of the tuyeres. Up to 800° the sulphur is principally absorbed by the oxides of iron from the sulphur-laden gases, while from 800° upwards the position is reversed, and the lime becomes the chief absorbent of the sulphur.

Reports of research work carried out during the past year by Dr. H. C. H. Carpenter (National Physical Laboratory), by Mr. J. C. Gardner (Birmingham), by Mr. F. Rogers (Cambridge), and by Mr. Gunnar Dillner and Mr. A. F. Enström (Stockholm), holders of the Carnegie research scholarships, were submitted. Dr. Carpenter dealt with the types of structure and the critical ranges on heating and cooling high-speed tool steels under varying thermal treatment.

In the light of the author's experiments the rationale of the advantageous presence of tungsten and molybdenum in high-speed tool steels appears fairly evident. The action of either of these elements consists in hindering, under certain conditions, and in altogether preventing, under suitably chosen conditions, changes in iron carbon alloys which would have for their result the softening of the material and its consequent unfitness for tool steel use. By suitable heat treatment it is possible to arrest the softening process at any desired stage, and thus obtain an alloy of any desired hardness. The metallographical results of the investigation are extremely interesting. They show that in spite of comparatively large percentages —up to 17 per cent. or 18 per cent.—of special elements, iron and carbon still remain as the all-important factors in determining the types of structure of high-speed tool steels. Except that the polyhedral or "austenitic" type of structure has never been obtained alone in a pure carbon steel, the types of the high-speed tool steels might all be obtained from pure iron carbon steels by appropriate thermal treatment. The austenitic structure appears to be that of the nose of the tool in actual use. Put briefly, the hardening of rapid tool steels at the present time appears to involve two factors, viz. (1) the widening, splitting, or lowering of the critical ranges by the special alloy element, and (2) the complete, or practically complete, suppression of the widened, split, or lowered range by a mild quenching, *e.g.* in an air-blast.

Mr. G. Dillner and Mr. A. F. Enström dealt with the magnetic and electric properties of sheet steel and steel castings. The results obtained have rendered it possible to make some comparisons as to the relative suitability of the different methods for producing a soft steel for electrotechnical purposes (sheet material). It has appeared that Bessemer steel has a lower magnetic quality than open-hearth steel. On comparing basic and acid open-hearth steel, the basic steel has been found to be preferable and scarcely inferior to Lancashire iron. The reason why the Bessemer material is inferior in quality to the open-hearth sheets may possibly be that the Bessemer steel has a greater opportunity of dissolving gases when the air is passed through the bath of molten metal. In general, basic steel does not contain such large quantities of silicon and manganese as acid steel, and at the same time it is possible to get a lower percentage of carbon in the first mentioned metal; these facts may cause the hysteresis loss to be lower in basic than in acid steel.

Mr. J. C. Gardner dealt with the effects caused by the reversal of stresses in steel, and Mr. F. Rogers submitted memoirs on troostite and on the heat treatment of steel.

It was announced that Andrew Carnegie research scholarships for this year, of 50*l.* each, were awarded to P. Breuil (Paris), Dr. H. C. H. Carpenter (National Physical Laboratory), E. G. L. Roberts and E. A. Wraight (London), and W. Rosenhain (Birmingham), and that scholarships, each of the value of 100*l.*, were awarded to H. C. Boynton (Cambridge, U.S.A.), L. A. Guillet (Paris), and W. H. Hatfield (Sheffield).

The council carefully examined the reports of the research work carried out by the holders of the Carnegie research scholarships during the past year, and decided that the report prepared by Dr. H. C. H. Carpenter (National Physical Laboratory) was deserving of the gold medal. The council also decided that special silver medals should be awarded for the research carried out conjointly by Mr. Gunnar Dillner and Mr. A. F. Enström (Stockholm). The researches submitted by Mr. Gardner and Mr. Rogers were highly commended. The medals were presented by Mr. Carnegie at the banquet on May 12 at the Hotel Cecil, when 500 gentlemen were present.

During the meeting it was announced that Mr. Carnegie would give to the institute a further sum of 5000*l.* to cover the cost of printing the reports submitted by the Carnegie research scholars.

HIGHER EDUCATION IN LONDON.

RECENT events inspire hope in the future of higher education in London. The report presented by Sir Arthur Rücker, F.R.S., principal of the University of London, at the celebration of presentation day on May 10, and the speech of Lord Londonderry in proposing "The Institution of Mining and Metallurgy" at the annual dinner of its members, are both highly encouraging and indicative of the growing importance attached in the metropolis to education of university standing, especially in science and technology.

Sir Arthur Rücker, in the course of his report, dealt in detail with the operations of the University of London, and was able to show that some of the preliminary work done since the re-organisation of the university has begun to bear fruit in the academic year now approaching its termination, and that the activity of the university has been extended in several directions. The question of the conditions of entrance to universities has been prominently before the public during the year, and a very important step has been taken by the Universities of Oxford, Cambridge, and London, which have agreed upon a scheme for the mutual recognition of the certificates given for their respective entrance examinations. Already twenty-five persons have been matriculated as students of London University under this agreement. Considerable progress has been made, also, with the project for the concentration of the teaching of the preliminary and intermediate studies of medical students in a few centres under the control of the university. Arrangements are in progress under the auspices of the university for establishing centres at University and King's Colleges, and Mr. Alfred Beit has given a munificent donation of 25,000*l.* in aid of the scheme for the establishment of a third centre on the South Kensington site. It is much to be hoped that this generous gift will be supported by other large subscriptions. It is a matter of vital interest to the public that the unique opportunities for medical education afforded by the great metropolitan hospitals shall not be wasted, and, if they are to be utilised, it is essential that the whole curriculum of medical education shall be easily accessible to London. It is necessary, continued Sir Arthur Rücker, that medical education shall receive public help similar to that which is ungrudgingly given to engineering. It is not too much to say that medical men do more unpaid work for the public than do the members of any other profession, and that, in return, less help has been given by the public to medical education, in London at all events, than to any other of the principal branches of applied science. Large as the gifts to the university are,

it is unfortunately true that much money is needed to make up for the neglect of university teaching in London in the past. Though the increase in the Government grant to university colleges will be of great value, the equipment of both University and King's Colleges needs improvement, and the salaries of the professors are quite inadequate. The whole question of retiring pensions, to which a private donor has just devoted 2,000,000*l*. in America, is untouched in London.

After the presentation for degrees at the University of London, there was a reception at Bedford College. The occasion is always one for the assembling of the friends of the higher education of women in London, and about five hundred guests were received by the principal, Mrs. James Bryce, and Mrs. Leonard Darwin. The students who were presented at the university included eight for science degrees. The college authorities are contemplating a great re-building scheme, for the lease of the present premises in Baker Street is almost on the point of expiring, and an appeal is being made for a quarter of a million sterling, of which 100,000*l*. would be devoted to endowing a college capable of accommodating five hundred students.

Lord Londonderry, in his speech at the annual dinner of the Institution of Mining and Metallurgy, referred to the work of the committee appointed by the Government to consider the coordination of the Royal College of Science at South Kensington with other institutions for higher scientific and technological instruction in London. An interim report has been presented by the committee. The Government has definitely informed the committee that, provided satisfactory arrangements can be arrived at for the due coordination of the work of the various higher scientific teaching institutions in London and elsewhere, and provided that guarantees are obtained for the adequate management of what will practically be a congeries of highly organised technical courses, and for the provision of a thoroughly satisfactory annual income for the upkeep of a great centre for this higher work, the Government is prepared to entrust the management of the Royal College of Science, including the Royal School of Mines, to a committee to be newly established for the purpose. This procedure, it is expected, will bring the work of the Royal College and School of Mines into the closest possible relations with that of the other higher teaching institutions, so that a higher degree of cooperation and coordination may be attained in this important portion of the educational field. Lord Londonderry announced that he has good grounds for believing that the Chancellor of the Exchequer has been considering the financial aspect of the new condition of things that will be brought about in regard to the Royal College of Science if the changes outlined actually take effect, and that a reasonable increase in the sums at present annually devoted towards the expenses of the Royal College of Science will be made. Thus the Royal College, in its immensely enhanced possibilities of usefulness owing to its large new buildings, will be able to bring to the common aim, not only its fabric and its excellent equipment, and, of course, its good will and prestige, but also a satisfactory annual income as a substantial contribution to what must be the heavy annual expenditure involved in the great work to be carried on for higher scientific and technological education in the metropolis.

As Mr. Haldane, the chairman of the committee referred to by Lord Londonderry, said on the same occasion, there is now a prospect of the establishment of such a school of mining and metallurgy as will make London the first city of the Empire in point of education in these matters.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Some five or six years ago a special committee was called together at Cambridge, and an effort was made to obtain the cooperation of the colleges and the town and county councils in a scheme for the improvement of the milk supply of Cambridge. The committee had as its primary object the eradication of tuberculosis, beginning with bovine tuberculosis, from the county of Cambridge. Concurrently it took up the question of the housing of cattle, the sterilisation of milk, the methods of storage and distribution of milk, and the question of what milk should be refused by the colleges and by private purchasers. All these points were considered, not only with regard to tuberculosis, but also in connection with other infectious diseases, *e.g.* diphtheria, scarlet fever, and typhoid fever. The Cambridge Town Council undertook to pay the expenses of a veterinary surgeon, and the following colleges undertook to consider the matter favourably, and in most cases offered a certain annual subvention:—Gonville and Caius, Trinity Hall, King's, Christ's, Sidney, Emmanuel, Downing, and Girton, but the larger colleges stood out, and the scheme fell through.

Prof. Woodhead, in an interesting article in the *Cambridge Review* of last week, raises the question whether some such scheme should not be revived, and points to the recent outbreak of scarlet fever, which was especially prevalent in one or two colleges, as an instance of a disease which might easily have been avoided if the community had taken proper precautions.

It is proposed to erect a building containing examination rooms on a site on the north-east corner of the museum grounds. At present the university is put to great cost in hiring rooms which, apart from their expense, are not well adapted for examinations. The syndicate appointed to consider this question estimates that for a sum of 7500*l*. it could provide for all examinations held in the university throughout the year, except, perhaps, for a week or two in June and December.

The Vice-Chancellor announces the generous offer of the Drapers' Company to find the sum of 5000*l*. towards the cost of a building for the department of agriculture provided that a further sum of 5000*l*. is raised by voluntary subscriptions by the end of the current year.

The long vacation course in pathology, public health, and pharmacology will begin on Monday, July 3. Special courses of lectures have been arranged on phagocytosis, by Prof. Woodhead, with the assistance of Mr. W. Malden; on illness caused by unsound food, by Mr. H. E. Durham; on diphtheria, agglutinins, precipitins and hæmolysins, by Mr. G. S. Graham-Smith; and on protozoa and protozoal diseases, by Dr. Nuttall. Further information about these courses may be obtained by writing to Prof. Woodhead, The Museums, Cambridge.

Special courses on physiology, osteology, human anatomy, and histology will be given during the long vacation by Mr. Barcroft and Mr. Cole, Dr. Barclay-Smith, Dr. A. Hill, and Mr. Manners-Smith. These will begin on July 5.

THE jubilee of Cheltenham Ladies' College was celebrated on Saturday last, and a new science wing was declared open. The new laboratories and lecture-rooms have been erected at a cost of 18,000*l*., and include rooms well equipped for the teaching of physics, chemistry, and botany.

THE following resolution was carried at a meeting of the council of the Royal College of Surgeons of England, held on Thursday last:—"That it be referred to the Committee of Management to consider and report as to the desirability of treating chemistry, physics, and biology as subjects of preliminary education, and of requiring that an examination in them should be passed before the recognition of the commencement of medical studies, and to report further as to the desirability of the two colleges approaching the Universities and other examining bodies with the view of adopting a five years' curriculum of professional study from the date of passing the Preliminary Science Examination."

AN entrance scholarship in science, value 48*l*. for three years, will be awarded by the council of Bedford College for Women (University of London) on the result of an examination to be held June 28–30. Full particulars can be obtained from the principal, and forms of entry must be received by June 12. The council, on the recommendation of the Reid trustees, will award the Reid fellowship in June to a graduate of the University of London who is also an associate of Bedford College. Applications should

be received by the hon. secretary of the Reid trustees by May 30. Miss Alice Ravenhill is to begin a course of lectures on May 18, at 4.30 p.m., on the "Teaching of Hygiene."

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, May 4.—Prof. R. Meldola, F.R.S., president, in the chair.—Notes on sodium alum: J. M. **Wadmore**. The author has confirmed the observations of Augé, Zellner, and Dumont as to the existence and certain of the properties of sodium alum.—Camphoryl-*pseudo*-semicarbazide: M. O. **Forster** and H. E. **Fierz**. This compound was obtained by reducing camphorylnitroso-*pseudo*-carbamide with zinc dust in dilute acetic acid; it condenses readily with aldehydes and ketones, yielding products characterised by high specific rotatory powers.—Some derivatives of anhydracetonebenzil: F. R. **Japp** and J. **Knox**. Descriptions of the condensation products of benzil with certain unsaturated ketones are given.—The dihydrocyanides of benzil and phenanthraquinone, part ii.: F. R. **Japp** and J. **Knox**.—A condensation product of mandelonitrile: F. R. **Japp** and J. **Knox**. It is shown that Minovici's compound, $C_{16}H_{12}ON_2$ (*Ber.*, 1899, xxxii., 2206), obtained by saturating mandelonitrile in dry ether with hydrogen chloride, is identical with the substance obtained by Japp and Miller by the action of hydrogen chloride on a solution of benzil in alcoholic hydrocyanic acid (*Trans. Chem. Soc.*, 1887, li., 29).—Action of hydrazine on unsaturated γ-diketones: F. R. **Japp** and J. **Wood**. The authors have used Paal and Schulze's reaction to distinguish the configurations of certain analogous unsaturated diketones. By this means they have obtained confirmatory evidence for the configuration assigned by Japp and Klingemann to the two modifications of $\alpha\beta$-dibenzoylstyrene and of dibenzoylstilbene.—The synthesis of substances allied to adrenaline: H. D. **Dakin**.—Methylation of *p*-aminobenzoic acid by means of methyl sulphate: J. **Johnston**.—The atomic weight of nitrogen: R. W. **Gray**. By the examination of (1) the relative densities and compressibilities of nitric oxide and oxygen, and (2) the decomposition of nitric oxide with finely divided nickel, a mean value of 14·006 (which is regarded as possibly too low) was found for this constant.—The methylation of gallotannic acid: O. **Rosenheim**. A penta-methyl-derivative was obtained, by methylation with methyl sulphate, and this on hydrolysis furnished a mixture of trimethyl- and dimethyl-gallic acids.—The interaction of hydrogen sulphide and sulphur dioxide: W. R. **Lang** and C. **Carson**. An investigation of Wackenroder's solution showed that the action of hydrogen sulphide produces first sulphur and water, and that by the further action of sulphur dioxide on sulphur polythionic acids are produced.—The formula of cyanomaclurin: A. G. **Perkin**. It is now found that the formula $C_{15}H_{12}O_6$ is to be preferred in place of $C_{15}H_{14}O_6$ formerly used.

PARIS.

Academy of Sciences, May 8.—M. Troost in the chair.—The increase of the rotatory power of fatty molecules in passing to the state of cyclic compounds: A. **Haller** and M. **Desfontaines**. A comparison is given of the rotatory powers of alkyl esters of β-methyladipic acid with the esters of the corresponding β-cyclopentanonecarboxylic acids, the rotations of the latter being found to be about thirty times those of the former. The densities and boiling points of the various esters under examination are also given.—On a new synthesis of oxalic acid: H. **Moissan**. It has been shown in a previous paper that whilst perfectly dry carbonic acid is without any action upon potassium hydride, in the presence of a minute trace of water the two substances react with the quantitative formation of potassium formate. It is now shown that if this reaction is allowed to take place at a higher temperature, 80° C., a mixture of potassium formate and oxalate is produced. The oxalic acid formed was separated, and its identity proved by analysis and numerous reactions.—Endoglobular pseudo-hematozoa: A. **Laveran**. As some of the normal elements of blood, more or less modified in their appearance, have on more than one occasion been mistaken for endoglobular hematozoa, a detailed account, with diagrams, is given of some of the more common cases leading to this error.—On the magnetic hysteresis produced by an oscillating field superimposed on a constant field: P. **Duhem**. A theoretical investigation completing a former paper on the same subject.—Geodesic and magnetic work in the neighbourhood of Tananarive: P. **Colin**. The triangulation of the rectangular section between the south and west of Tananarive has been completed at sixty-seven points. At the same time magnetic observations have been carried out at twenty-six stations, a tabular view of the results being given.—The oscillations of railway carriages on entering and leaving a curve: Georges **Marié**.—Observations of the Giacobini comet (1905 *a*) made with the large equatorial of the Observatory of Bordeaux: Ernest **Esclangon**.—On Voss surfaces and non-Euclidean geometry: Alphonse **Demoulin**.—On the indeterminate equation $x^a+y^a=bz^a$: Ed. **Maillet**.—On some points in the theory of numbers and the theory of functions: Georges **Rémoundos**.—On a new spectrum observed in gadolinium: G. **Urbain**. The author, having obtained a specimen of gadolina of such purity that twenty successive fractions gave the same value for the atomic weight, has examined the spectrum. There is no absorption spectrum in the visible region, but there are some strong absorption lines in the ultra-violet. The ultra-violet phosphorescence given by this gadolinium in the kathode rays proved to be the same as that attributed by Sir W. Crookes in 1898 to a new element named by him victorium. The author proposes to submit the question as to the identity of gadolinium and victorium to further experiment.—On the triboluminescence of potassium sulphate: D. **Gernez**. The experiments of the author are not in accord with those of Bandrowski on the same subject. The emission of light appears to be the result of breaking up of crystals already formed, and if due precautions against shock be taken, the phenomenon is not observed at the moment of separation of the crystals from their mother liquor.—The specific volume of a liquid in a capillary space: M. **Ponsot**.—On the electrical resistance of metallic wires for high-frequency currents: André **Broca** and M. **Turchini**. The authors have compared the resistances obtained experimentally with those calculated from Lord Kelvin's formula. For non-magnetic metals, copper and platinum, the deviations from the law calculated by Lord Kelvin are small for moderate frequencies. These deviations, however, are greater than the experimental error, and follow a definite law.—A new method of calculating the exact molecular weights of liquefiable gases from the experimental determination of their densities: Philippe A. **Guye**. The method described, the detailed proof of which is reserved for a later paper, has been applied to the cases of carbon dioxide, nitrous oxide, sulphur dioxide, hydrochloric acid, and acetylene. The values for the atomic weights of carbon, hydrogen, sulphur, and chlorine agree very closely with those determined by chemical methods. The value for nitrogen (14·006) is lower than the value deduced from chemical data (14·04), and there is reason to suppose that the latter is too high.—The action of potassammonium upon barium bromide: A. **Joannis**. The reaction has been found to be in accordance with the equation

$$BaBr_2+2NH_3K=2KBr+H_2+Ba(NH_2)_2.$$

—On the colloidal forms of ferric chloride: G. **Malfitano**.—The electrolytic reduction of the nitrocinnamic acids: C. **Marie**. Meta- and para-nitrocinnamic acids give by electrolytic reduction in alkaline solution the corresponding azoxy acids. The position of the nitro or the amino group has a marked influence on the ease with which the hydrogen is added to the lateral chain. Para derivatives give hydrocinnamic compounds much more easily than the corresponding meta compounds.—The action of carbon monoxide upon silver oxide, and its application to the determination of small quantities of carbon monoxide in the atmosphere: Henri **Dejust**. Silver oxide, dissolved in ammonia, is immediately reduced by traces of carbon monoxide. The author proposes a colorimetric method based on this reaction for the estimation of minute traces of carbon monoxide in the air.—On strontium ammonium:

M. **Rœderer.** Strontium ammonium is prepared in a similar manner to the compounds of ammonia with barium and calcium, and has the analogous formula $Ba(NH_3)_6$.—Osmosis through tubes of fused quartz: G. **Belloc.** The passage of gases through quartz tubes appears to be the result of a kind of devitrification caused by moisture and high temperature, the tendency to crystallisation being clearly made out under the microscope.—On a new osmium compound and a new reaction for osmium: Piñerûa **Alvarez.** The process is based on the formation of a green compound of hydriodic acid and osmium iodide of great tinctorial power.—The action of alkalis on aqueous solutions of acetol: André **Kling.** The behaviour of acetol on neutralisation with bases seemed to point to its being a pseudo-acid, and this view was confirmed by a study of the changes in its electrical conductivity.—On the saccharification by malt of artificial starch: Eug. **Roux.**—The action of metal ammoniums on the halogen derivatives of methane: E. **Chablay.** The equation

$$2NH_3Na + 2CH_3Cl = 2NaCl + CH_4 + CH_3.NH_2 + NH_3$$

was found to represent the reaction between methyl chloride and sodium ammonium. The reactions with chloroform and iodoform were more complicated.—On the use of metal ammoniums in organic chemistry: the formation of primary amines: Paul **Lebeau.**—On a new method of characterising the purity of milk based on the estimation of the ammonia: A. **Trillat** and M. **Sauton.** Ammonia should not be present in normal pure milk; its presence is evidence of pollution.—On polymorphic transformations by mechanical action: Fred. **Wallerant.**—On the state of preservation of minerals in arable earth: M. **Cayeux.** In opposition to the views of MM. Delage and Lagatu, the author finds that minerals in an altered state are always present in arable earth.—New species of endophytes of orchids: Noël **Bernard.**—The culture of Morchella: Ch. **Répin.**—The elective action of chloroform on the liver: M. **Doyon** and J. **Billet.**—On the toxicity of the urinary alkaloids: H. **Guillemand** and P. **Vranceano.**—The estimation of the sugar in the blood at the moment of accouchement in the goat without udders: M. **Porcher.**—The influence of sexuality on the nutrition of *Bombix mori* at the later stages of its evolution. The localisation of the glycogen, fat, and soluble albumen in the course of nymphosis: C. **Vaney** and F. **Maignon.**

DIARY OF SOCIETIES.

THURSDAY, May 18.

Royal Society, at 4.30.—On Lesage's Theory of Gravitation and the Repulsion of Light: Prof G. H. Darwin, F.R.S.—The Atomic Weight of Chlorine; an Attempt to Determine the Equivalent of Chlorine by direct burning with Hydrogen: Prof. H. B. Dixon, F.R.S., and E. C. Edgar.—The Flow of the River Thames in Relation to British Pressure and Rainfall: Sir Norman Lockyer, K.C.B., F.R.S., and Dr. W. J. S. Lockyer.—Thorianite, a New Mineral, from Ceylon: Prof. W. R. Dunstan, F.R.S., and G. S. Blake.—A Modified Apparatus for the Measurement of Colour, and its Application to the Determination of the Colour Sensations: Sir William Abney, K.C.B., F.R.S.—Further Observations on the Germination of the Seed of the Castor Oil Plant (*Ricinus communis*): Prof. J. Reynolds Green, F.R.S., and H. Jackson.—On the Efferent Relationship of the Optic Thalamus and Deiter's Nucleus to the Spinal Cord, with Special Reference to the Cerebellar Influx Theory (Hughlings Jackson) and the Genesis of Decerebrate Rigidity (Sherrington): Dr. F. H. Thiele.—On Reciprocal Innervation of Antagonistic Muscles. Eighth Note: Prof. C. S. Sherrington, F.R.S.—The Structure and Function of Nerve Fibres. Preliminary Communication and Addendum: Prof. G. THURSDAY, MAY 25, 1905.

THE ANOPHELES MOSQUITOES OF INDIA.

A Monograph of the Anopheles Mosquitoes of India. By S. P. James and Dr. W. G. Liston. Pp. 132 and plates. (Calcutta and London: Thacker and Co.) Price 24*s.* net.

THERE is one feature in which this book far surpasses any other devoted to mosquitoes, viz. the coloured plates. The authors and their artist, Dr. Turkhud, are to be congratulated on the excellence of these pictures. It will be now possible to compare an Indian Anopheline with a plate, and with practical certainty to be sure of its identity. The same could not be said of any representations of mosquitoes hitherto produced. These plates are beautifully executed, and depict faithfully the bands on the palpi, the spots on the wings, and the leg markings. It is a pity that some few Anophelines are not represented, but of these we have, of course, the systematic description.

The book is divided into two parts: (1) general, (2) systematic. The first chapter gives a general account of mosquitoes, egg, larva, nymph, and external anatomy of the imago. The description is clear and adequate for medical men, for whom the book is primarily written. We think perhaps a short account of the internal anatomy might have been added, as a knowledge of this is so important. The chapter ends with a short account of Theobald's classification of mosquitoes, which the authors are unable to accept. Instead of dividing the subfamily Anophelina into twelve genera as Theobald has done, they place them all (at least the Indian ones) in the old genus Anopheles. We cannot help thinking that this, in spite of some of the difficulties of Mr. Theobald's classification which they point out, is a retrograde step. The authors deal with a total of twenty-four Indian species; the total number of Anophelines, however, now amounts to nearly a hundred, and, to say the least, it would be very inconvenient, if not impossible, to deal with these if we placed them all in a single genus. In some of these, *e.g.* Lophoscelomyia, Christya, the difference in scale structure is so marked from, for example, a typical Myzomyia that we prefer to follow Mr. Theobald and put them in separate genera. Again, we do not know whether the authors would propose, ignoring scale structure, to arrange the rest of the Culicidæ in a single genus, Culex, and take no notice of the obvious differences in scale structure, *e.g.* between Mucidus and Culex, or between Stegomyia and Culex. We think, to be logical, they should do so, and try to classify them by palpal bands and leg markings; but this would be well-nigh impossible. We think the authors would have made their position more secure if they had been content with placing in the same genus only those in which they failed to recognise the differences in scale structure defined by Mr. Theobald. It may be granted that doubts sometimes arise, but we cannot regard this as an excuse for merging into a single genus those in which the differences are well marked and easily appreciable.

The second chapter contains a synoptic table of the Indian species of Anophelines, based upon the author's classification according to palpal bandings, wing spots, and leg markings; the chapter concludes with a description of the method of identifying Anopheline larvæ. The essential points are very clearly set forth, and there follows a classification—a modification of that originally constructed by Stephens and Christophers. One point noticeable as showing that even all the Indian Anopheline larvæ are as yet unknown is that the table only contains eighteen species, whereas the table of imagines contains twenty-four. This table should be of great assistance in helping actual workers in identifying their catch of larvæ from any source.

The third chapter is devoted to the habits of Anophelines. These most interesting questions are, as the authors admit, only beginning to be studied, and now that a book of this kind enables observers to identify their mosquitoes, we may expect much light on these questions—questions of vital importance, but to which many pay no attention. One of the most interesting problems is the distance of flight of Anophelines. Christophers and myself found in Africa instances which proved conclusively that normally the flight of Anophelines was quite a restricted one, to be counted in yards and not in miles, as was not uncommonly stated. A striking example of this we found in the central portion of Freetown, Sierra Leone. Although we lived there for several months during the dry and rainy seasons, we never discovered Anophelines in our rooms, yet a quarter of a mile away they existed in myriads in the native huts; and many other similar instances were observed by us. Yet in Mian Mir observations are quoted to show that *P. fuliginosus* will on occasions fly two and a quarter miles, and *M. rossii* three-quarters of a mile. But, of course, the conditions at Mian Mir are very different—in one case an open plain, in the other a crowded town. Closely bound up with this problem is the question of dispersal of Anophelines. Two of the most important means are (1) by flight, (2) "by a gradual spreading, by short stages, from areas in which they are abundant." This latter method is, it seems to us, one of the most important and overlooked by those who have no intimate knowledge of mosquito habits, but who readily draw up schemes for their wholesale destruction. We agree with the authors when they state, "observers who consider that Anopheles can be materially reduced in numbers by the obliteration of all breeding places in the immediate vicinity of dwellings, rely chiefly upon the suppositions that the range of flight of these insects is very limited and that they do not disperse any considerable distance from their breeding grounds. It would appear from the observations just recorded that such suppositions are incorrect, and if this is so, the task of materially reducing the number of Anopheles in any place will undoubtedly be one of great magnitude."

Again, granted that Anophelines have been diminished in numbers in a certain area, it by no means follows that the malaria will be diminished. We could furnish many instances observed by us in Africa where Anophelines were extremely scanty (but present) yet the malarial index was high. In fact, it is not *always* possible to trace any relation between the number of Anophelines and the value of the malarial index, although on the contrary it often is so. Finally, we may point out that we have at our disposal an accurate and easily applied method of determining whether anti-mosquito measures have diminished malaria. It is now universally accepted by medical men, but not generally known to the layman, that the great source of malaria in the tropics lies in the native children, who to the outward eye show no signs of ill-health, though they contain in their blood malarial parasites. The malarial index or endemicity is the percentage of children under ten years of age that harbour parasites. It is not uncommonly 100 per cent.

If, then, the anti-malarial measures have reduced malaria, this figure must decrease. If malaria has been abolished it must be zero. (It is hardly necessary to state that, in determining this index, children of the same age must be selected for comparison, and the comparison must be made at the same time of the year before and after operations; such precautions are obvious, and are, of course, always taken by those engaged in such observations.) To sum up, no facts are convincing where this proof is not adduced. If the malarial endemicity is reduced to zero, then anti-mosquito measures have been completely successful—but not until then.

Let us return, however, to the book. We think it would have been advantageous, considering the great importance of the subject, if the authors had compiled a tabular statement of those species that are known to transmit malaria *in nature,* though the data on this point can be found by search. At present, then, out of twenty-four Indian Anophelinæ it has only been shown that three convey malaria in nature, viz.:—*M. culicifacies,* by Stephens, Christophers, and James; *M. listoni,* by Stephens, Christophers, and James; *P. fuliginosus,* by Adie; and we know with practical certainty that *M. rossii* does not. The third chapter contains many interesting details of larval life, but it is to be hoped that many observers, using this book as their guide, will study the subject further and fill up the many lacunæ.

Chapter iv. is devoted again to the vexed question of classification. Then follows part ii., containing the systematic description of each species. The descriptions are excellently done, clear, and sufficient, and not overloaded with details which terrify the already overburdened medical man in the tropics. In fact, this book admirably fulfils the object of enabling "medical men engaged in tracing the connection between mosquitoes and human disease to identify and speak with precision of the species implicated." These words are attributed to Prof. Ray Lankester, and if they represent his words we cannot but think that the elaborate monograph of the Culicidæ, excellent as it is, issued by the museum authorities has not had this result. The majority of medical men in the tropics can ill afford the time or inclination to read these detailed descriptions. We think if the museum authorities would issue concise but adequate accounts of, say, the Anophelinæ only, medical men would be greatly helped. For a few shillings the United States authorities publish excellent bulletins on various subjects, *e.g.* the ticks, the flukes, and so forth, but if a medical man in British possessions wants to identify the species of tsetse-fly he is working with he must buy a monograph issued by the museum costing fifteen shillings. If he wants to know anything about ticks, the museum leaves him in the dark. Seeing what medical men have done recently in elucidating malaria, sleeping sickness, and, most recently of all, tick fever, we think they might reasonably expect some help in return. We would point out finally one small matter which might be corrected in a future edition. In the list of illustrations only i–x are mentioned, though these number xv at least. The arrangement of the plates is erratic, *e.g.* v, xi, vi, xiv, vii, &c., so that they are very difficult to find. The proofs have evidently been carefully read, and we have detected no error of any importance.

The authors have had the great advantage of describing species caught on the spot and studied under their natural surroundings. We trust somebody will be found in Africa to write an equally good text-book of African Anophelines.

We think that all medical men in India will feel grateful to the authors for this excellent work.

J. W. W. STEPHENS.

EXERCISES IN PHYSICS.

Notes and Questions in Physics. By Prof. John S. Shearer. Pp. vii+284; illustrated. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1904.) Price 7*s*. 6*d*. net.

THE present volume has been written to take the place of a similar book prepared several years ago by Prof. C. P. Matthews and the author. Actual experience in the class-room indicated the desirability of certain extensions and changes in the text, and also of many explanatory notes and solutions.

The book is, in reality, a collection of problems—many of which have been selected from examination papers—together with occasional hints with regard to solving them, and very brief introductory paragraphs to each section which explain the principal technical terms referred to therein. It will be easily understood, therefore, that the book is not intended to take the place of regular text-books, lectures, or of laboratory practice. It is designed, indeed, to accompany these. The supply of problems in many text-books is exceedingly scanty—the present volume amplifies the supply. It will be found of great service to the teacher in suggesting problems to set as class work. As no answers are given, there will be less temptation to the teacher merely to quote the selected problems; anyone who is alive in his subject will modify them to suit his

own preferences. The absence of answers makes the book of no use to the private student who requires some check on the work he does. On the whole, we think that the utility of the book would be increased by the addition of these; or, if this is not favoured, then by their publication in a separate volume.

The whole ground of physics is covered, including mechanics. The general difficulty is only slight. By far the largest number of the problems could be tackled by a first-year university student. In mechanics very many are even of matriculation standard; thus, "The Washington Monument is 169 metres high. In what time will a stone fall from top to bottom?" Mingled with these are a few requiring the calculus. Many require only a qualitative answer; thus, 'Explain why it is difficult to walk up an icy hill." These remarks are equally true of the other sections; thus, in electricity, the following is a commonly occurring type of question:—"Two copper wires are of the same cross-section, but one is twice as long as the other. Compare their resistances." Indeed, this question illustrates the general character of the book very well. Take each clause of an ordinary text-book and express it in question form—that seems to have been the mode of formation. We miss the bright sparkle of genius which flashes out from the examination papers of many of the examiners that we know. Still, we think, and we have said, that many will find it a very useful book.

Turning next to the hints, which, we think, might be multiplied with advantage, these are not always above criticism. Take, for example, the following:—

"Prove that a gun free to move backward and the bullet fired from it have the same momentum when the bullet leaves the gun. Note: Action and reaction are equal and opposite. Force on gun = force on bullet.

$$M_g A_g = M_b A_b \text{ [A = acceleration]}$$

Multiply by t

$$M_g V_g = M_b V_b."$$

We are of opinion that equality of the two momenta is the fundamental fact which can be proved only by experiment. The operation of changing from a variable acceleration to the change in velocity is inadequately represented by a multiplication by the time.

The arrangement of the problems seems to have been imperfectly attended to; very many questions are to be found in sections with which they have nothing to do. For example, under the head "Colour" occur a series of questions such as "Why does an object appear equally bright at all distances from the eye?"

A series of useful tables completes the volume. The numerical constants given are not always scrupulously exact. For example, log $\pi = 0{\cdot}497150$ and not $0{\cdot}497149$ (as given) when only six figures are to be retained. Again, why should a student (or teacher) be misled into taking log π^2 as $0{\cdot}994299$ when the much simpler number $0{\cdot}994300$ is more exact? There are two other examples of this on the same page. This is the kind of number which, if quoted at all, ought to be checked and re-checked until the author is sure that he has it right.

MATHEMATICAL METAPHYSICS.

Principien der Metaphysik. By Dr. Branislav Petronievics. Vol. i., part i. Pp. xxxi+444. (Heidelberg: Carl Winter, 1904.) Price 15 marks.

THIS is the first instalment of a new work on metaphysics. It discusses only general ontology and the formal categories (in other words, the general ontological and the quantitative problem). The second part of the same volume, we are informed, will deal with the qualitative and hyper-metaphysical problems, and the second volume will then go on to cosmology and psychology.

The author's guiding principle is expressed in the motto, "Correct mathematical ideas are the key for the solution of the riddle of the universe." We doubt if this will command the acceptance of any metaphysicians whose interests are not primarily mathematical. Mr. Balfour, in a well-known passage, has pointed out how often the battles of theology are decided beyond the borders of that study; it is a little hard if the metaphysician, who contemplates all time and all existence, is to be fettered by the geometrical views of his age, and before he makes any headway in *prima philosophia* must study closely the hundred-page account of the new geometry "with 3 tables containing 56 geometrical figures."

We doubt in particular whether ordinary metaphysicians will ever accept the "discrete" or atomic view of space here given, however fashionable it may be among modern mathematicians. That view goes back to the Arabic school of the Mutakallimun. Dr. Petronievics adopts, with some slight differences, the development of the theory advocated by Giordano Bruno. He distinguishes two kinds of "point," *Mittelpunkt* (*der reale mit Inhalt erfüllte Punkt*) and *Zwischenpunkt* (*der irreale die leere nichtseiende Lücke darstellende Punkt*). The discussion of time follows the same atomic lines. The plain man wonders in what fashion precisely his old friend "Achilles and the tortoise" is to be dealt with on these principles. (That fallacy, it is true, appeals in the first instance to those who combine an atomic view of Time with a non-atomic view of Space, but it has surely its difficulties for any who regard either Time or Space as discrete.) The same guileless innocent, while understanding readily the general data which enable a Kelvin to calculate the approximate size of "atoms" of water, does not see quite so readily how we can ever hope to reach the data for determining the size of atoms of impalpable Time or Space. Nor, again, does he see the special benefit of abolishing the old Euclidean point in favour of the new one endowed with both position and magnitude, when to all intents he is compelled, a moment later, to revive in the term *Zwischenpunkt* the "point" of his earliest geometrical affections—"that which has position but *not* magnitude"; and he recalls the Horatian tag, "*Expelles furca, tamen usque recurret.*"

Still, the discussion contained in this volume is stimulating, and considerable dialectic power is displayed. One will watch with interest in the later volumes whether the author succeeds in dealing with

his various problems without always recurring to the mathematical point of view. Unfortunately, one word must be said regarding the typography. The present reviewer has seldom read a book so badly corrected for the press. There are two pages of corrigenda; but a full statement of all the small misprints would with difficulty be contained in four or five pages more. If it is not *c* for *o* or *e*, it is *u* for *n*, or *l* for *t*, or *b* for *h*, or *das* for *dass*. This is the more to be regretted because—granted the author's point of view—the *i*'s of the philosophy are quite carefully dotted.

BRITISH MINERALS.

A Handbook to a Collection of the Minerals of the British Islands in the Museum of Practical Geology. By F. W. Rudler, I.S.O. Pp. x+241. (London: H.M. Stationery Office, 1905.) Price 1*s*.

SINCE his retirement from the post he so long and efficiently held as curator of the Museum of Practical Geology, Mr Rudler has installed in that museum a collection illustrative of the modes of occurrence of British minerals. The museum has long possessed collections of British rocks, fossils, and ores, the last named arranged under the various metals which they contain. In the new collection, which is neatly arranged in twelve table-cases, the minerals found in each district are brought together; half the space is allotted to Cornwall and Devon, one-eighth to Scotland, Ireland, and the Isle of Man, and the remainder to the rest of England, the divisions being roughly according to the several mining districts, with a general group for the minerals of the Neozoic strata. The specimens, to the number of 1652, have mostly been selected from the Ludlam collection, which was bequeathed to the museum in 1880; though mostly small in size, they are of excellent quality. In addition to the name and locality attached to each specimen, there are many explanatory labels in the cases, and the present volume admirably serves the purpose of a guide to the collection.

The volume is by no means a tedious catalogue or descriptive list of all the individual specimens, but is rather an extremely readable and interesting account of the mode of occurrence and history of the more common British minerals, especially those which are of economic importance. Instead of long descriptions of the characters of species, much is said of their paragenetic relations, and many valuable suggestions are made as to their possible modes of origin. The book will therefore be found interesting and instructive not only to mineralogists, but also to geologists and miners; whilst quite apart from the collection, for which it is primarily intended, it will have a permanent value as a treatise. In this connection mention may be made of the numerous and extremely valuable references to original authorities consulted in the preparation of the work.

The mode of treatment is a novel one, and necessarily involves a certain amount of repetition, especially in the case of some of the more commonly occurring minerals, such as quartz, calcite, galena, &c., which may be found in almost all the different districts; but this repetition is not tedious. As an example, the district of Cornwall and Devon may be taken, in which the main groups are as follows:—cassiterite, minerals associated with cassiterite, copper sulphides and sulpho-ferrites, copper-bearing minerals of the gozzans, arsenates and phosphates of the copper-gozzans, ores of lead, zinc, antimony, &c., sulphides and sulpho-salts, ores of iron, &c., minerals of the rarer metals, the spars of the mineral veins, miscellaneous minerals.

Apart from a few minor misprints, the only point which calls for criticism is that undue importance seems to have been attached to many quite trivial and local names. As for the printing, there is certainly much room for improvement; the lines are so badly broken that it is surprising that the whole did not fall to pieces in the course of printing.

L. J. S.

OUR BOOK SHELF.

Moths and Butterflies. By Mary C. Dickerson. Pp. xviii+344; with 200 photographs from life by the author. (Boston, U.S.A., and London: Ginn and Co., n.d.) Price 5*s*. net.

THIS is a prettily got-up book, intended for the training of classes in "nature-study," with reference to a considerable number of common and conspicuous North American butterflies and moths, the life-history of which is very fully described and illustrated. The concluding chapter, on collecting, keeping, and studying, recapitulates the points to be noted in practical observations on the insects themselves.

To English readers the book will be useful for the information it supplies about American forms, and also as indicating a similar method of study for British insects, but many of the species here noticed are much larger and more conspicuous than those likely to fall under our own observation, among them being several species of Papilio, and large Saturniidæ.

The figures, of which (including apparatus, &c.) there are 233 in all, are generally very good, though some are indistinct. The frontispiece, representing a Smerinthus at rest, and Fig. 17, on p. 147, representing a procession of the young caterpillars of Saturnia, may be specially noticed. But it looks odd to see a Smerinthus closely allied to our own *S. ocellatus* called "a most beautiful little moth" (p. 232); and, though we do not object to the use of appropriate English names, we are sorry to see on p. 231 a Sphinx allied to *S. convolvuli* called "the Humming-Bird Hawkmoth," a name by which the very different *Macroglossa stellatarum* has been known all the world over, ever since the commencement of the study of entomology.

We had expected to find some notice of the gipsy moth, the crusade against which has recently been given up in America in despair, but find only a passing reference. A few British species are noticed, such as *Vanessa antiopa*, called in America the mourning cloak, a translation of its German name; *V. atalanta*, *Pieris rapae*, &c.

A great deal of useful general information is given in the book, and it seems on the whole to be careful and accurate. One statement, however true in the abstract, ought not to have been made without qualification or explanation in a popular book. On p. 267 we read, "We are familiar with the fact that all living

creatures develop from eggs." Further comment is needless.

Although published in 1901 and mentioned in the *Zoological Record* for that year, this book has not previously been brought under our notice.

Second Stage Magnetism and Electricity. By Dr. R. Wallace Stewart. Second edition. Re-written and enlarged. Pp. viii+416. (London: W. B. Clive.) Price 3s. 6d.

This book is primarily intended to serve the purposes of a candidate preparing for the second stage examination under the Board of Education (secondary branch). In reading it, we have by no means made our first acquaintance with Dr. Stewart, and the perusal has left us of our old opinion that, whether regarded as text-books intended to prepare a student for a particular examination or as a source of culture, the books prepared by the author can be very earnestly recommended. He is a lucid and accurate writer. He knows where to draw the line so that an elementary student shall not be repelled by the complication of a subject.

The present volume is brought up to date. The importance of the field—that is, the medium surrounding an electrified conductor or magnet—is insisted on; perhaps even their importance is emphasised too much. The tendency of modern thought amongst physicists is to restore to a conductor part, at any rate, of the position that it held in pre-Maxwellian days. The dielectric plays a most important part—that is a position, won for it by Maxwell, which it can never lose. At the same time, one should not lose sight of the fact that there *must* be some mechanism at the ends of a line of induction, and to-day that mechanism is being studied under the name of *electron*. The electron is an essential part of a conductor, and the complete phenomena of electricity are not fully accounted for without including it.

The volume is almost entirely re-written. It is not surprising, therefore, that there are some unfortunate slips which have escaped the vigilance of the reader. As these are misleading, we will state that on the bottom of p. 33 "positive" and "negative" should be interchanged. The following phrase (p. 42) is very misleading:—"The portions of those walls, which are, as it were, in the shadow of these objects, possess no induced charge." We think that the first thirty pages might be improved in any later edition. Considerable care has evidently been taken; yet in many cases confusion is introduced by the neglect of some tiny detail. Thus, in describing the attraction and repulsion of a pithball with subsequent re-attraction, *if in the interval it comes in contact with an earth-connected body*, the phrase that we have put in italics is omitted; and in several cases where a body is touched to earth it is not explicitly said whether the contact is to be broken before a succeeding operation is performed or not. Why is it "evident" (p. 16) that doubling a charge will double the force it exerts on another charge?

Memoria sobre el Eclipse Total de Sol del día 30 de Agosto de 1905. By D. Antonio Tarazona. Pp. 125. (Madrid: Bailly-Bailliere E. Hijos, 1904.)

Those who are familiar with the Spanish language and have made up their minds to go abroad and see the approaching total eclipse of the sun will find in this book a great amount of useful information relating to this interesting event. The work is issued from the Madrid Astronomical Observatory, the director, Francisco Iñiguez, having contributed a brief preface, and contains full particulars concerning the elements of this eclipse; in fact, it might be considered a treatise on the subject, so complete is the information. In addition to a great many data which will be of special use to astronomers, there will be found a very full list of towns, in alphabetical order, at which totality occurs, with the times of the different phases of the eclipse. More generally useful perhaps will be found the maps at the end of the volume. These include a map of the world showing the position of the track from the commencement to the end of totality over the earth's surface. A second illustrates on a larger scale the Spanish portion of the track, with special lines showing the times of occurrence and duration of totality. The third, on a much larger scale (1 : 1,000,000), indicates that part of Spain alone over which the shadow sweeps, and is very complete as regards names of places, railways, &c. Lastly, two star charts are added, one showing the position of the eclipsed sun among the stars, and the second a key map to this chart giving the designations of the stars and planets in this region.

Visitors to Spain will do well to supplement their literature by securing this volume, and thanks are due to the Madrid Observatory for producing so useful a book so far in advance of the event.

Naturalistische und religiöse Weltansicht. By Rudolf Otto. Pp. 296. [Tübingen: J. C. B. Mohr (Paul Siebeck), 1904.] Price 3 marks.

No better book than this could be recommended to the young philosophical or theological student who wishes to obtain a clear and comprehensive view of the debatable ground where science, philosophy, and theology meet. The author is well read, a skilful debater, a vigorous writer; and as handbooks ought not to be unnecessarily multiplied, it is to be hoped that this one will be translated.

Like many other works in defence of religion in general, the book is not so strong on the constructive as on the critical side. The author refers with approval to the attitude of Kant when he solved certain contradictions or antimonies by a reference to the world of things in themselves. As this is precisely the point where Kant's philosophy is most seriously questioned, the argument probably suffers to that extent. But, on the other hand, the author fully realises the unity of the various phases of the one problem religion *versus* naturalism, and the harm which has been done by concentrating the attention on one phase (*e.g.* the question of miracles) as if it were the whole.

The work is valuable mainly for its survey of the most interesting biological theories of the last century, from Darwin, Häckel, Weismann, down to Wolff, Korschinsky, Driesch. The philosophical development of this last writer is sketched in an enlightening fashion. With regard to the general theory of development and "descent," the author comes to the conclusion that with the confirmation of any such theory only something relatively external is given, a clue to creation, which does not so much solve its problems as group them afresh. The index at the end of the work gives an explanation of the more difficult terms employed by modern theorists.

An Introduction to Projective Geometry and its Applications. By Dr. Arnold Emch. Pp. vii+267. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 10s. 6d.

This text-book of modern projective geometry forms an admirable introduction to the subject, and should be known to all who are interested in this branch of mathematics. The first chapter deals with the general properties of projective ranges and pencils and their products, including harmonic and perspective projection, and the projective properties of the circle. Then

follows an investigation of collineation in a plane, comprising perspective transformations, and the linear transformations of translation, rotation, and dilatation, with combinations of these. The intimate relation that exists between projective and descriptive geometry is shown. The third chapter gives the general theory of conics, the projective properties of the circle being extended to conics by perspective transformations. The next chapter deals with pencils and ranges of conics and their products, and especially with cubics, the latter being classified under the five standard types by the help of the Steinerian transformation. Throughout the book analytical and geometrical methods are employed side by side, some portions of the subject being better suited to the former treatment; moreover, the analysis affords excellent illustrations of modern analytical geometry. The main purpose of the author has been to develop the subject in regard to its practical applications in mechanics, and the last chapter is devoted to such examples. Thus we find problems in graphic statics, plane stresses, and in the stress ellipse of an elastic material, and there is an interesting account of various linkages by means of which linear and perspective transformations can be mechanically obtained. The book is excellently got up in every way, and the diagrams are quite perfect and may well serve as models of what such figures ought to be. The author is a very clever draughtsman, and his skill as a writer is equally pronounced.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Fictitious Problems in Mathematics.

IN my younger days it was well recognised that such statements as "perfectly smooth" and the like were mere conventional phrases for designating an ideal state of matter, which was assumed to exist for the purpose of simplifying the mathematical conditions as far as possible. Nobody can learn mathematics without working out a large number of problems and examples, and in order to make these sufficiently easy for the beginner, various fictitious hypotheses have to be introduced.

Similar objections would apply to the phrase "frictionless liquid"; but it would be impossible for anyone to learn hydrodynamics without first studying the mathematical theory of this fictitious form of matter. In fact, the introduction of viscosity leads to such formidable difficulties, that nobody has yet succeeded in solving such a simple problem as the motion due to a doublet situated at the centre of a sphere; and the solution, if it could be obtained, would throw much light on the mode of attacking more difficult problems. A. B. BASSET.

May 28.

IN NATURE of May 18 the wording of a problem set near the beginning of my "Rigid Dynamics" is rather adversely commented on. In the problem a man is described as walking along a perfectly rough board which rests on a smooth table, and the criticism is that the two suppositions are inconsistent; but this depends on what is meant by the words used, and perhaps I may be allowed to make an explanation.

When bodies are said to be perfectly rough, it is usually meant that they are so rough that the amount of friction necessary to prevent sliding in the given circumstances can certainly be called into play. In art. 156 of the treatise on dynamics, just after the laws of friction have been discussed, the words "perfectly rough" are defined to have this meaning. The board in question has therefore no special peculiarity. All that is stated is that the coefficient of friction between the man and the board exceeds a certain finite quantity.

The board rests on a smooth table, but the coefficient of friction now depends on both the board and the table, and this may be quite different from that between the man and the board. There is nothing amiss in supposing this coefficient to be zero. One way of effecting this experimentally would be to polish the table and remove all roughnesses from it. This was the plan indicated.

Where, then, is the inconsistency?

By using the ordinary abbreviations of language, the wording of the question has been made concise, and thus attention was specially directed to the dynamical principle involved in the solution.

The problem has been understood by so many students in the sense above described, and worked without a single objection having been raised, that I think the meaning must be perfectly clear. Indeed, I cannot imagine what other meaning it could have. E. J. ROUTH.

May 20.

On the Spontaneous Action of Radio-active Bodies on Gelatin Media.

IN the course of some experiments on the formation of unstable molecular aggregates, notably in phosphorescent bodies, I was led to try whether such dynamically unstable groupings could be produced by the action of radium upon certain organic substances. It will scarcely be necessary to enter here into an account of the many speculative experiments which I have at one time or another tried, but it will suffice if I describe, as briefly as possible, the experiment which, amongst others, has led to a very curious result, and that is the effect of radium chloride and radium bromide upon gelatin media, such as those generally used for bacterial cultures.

An extract of meat of 1 lb. of beef to 1 litre of water, together with 1 per cent. of Witter peptone, 1 per cent. of sodium chloride, and 10 per cent. of gold labelled gelatin, was slowly heated in the usual way, sterilised, and then cooled. The gelatin culture medium thus prepared, and commonly known as bouillon, is acted upon by radium salts and some other slightly radio-active bodies in a most remarkable manner.

In one experiment the salt was placed in a small hermetically sealed tube, one end of which was drawn out to a fine point, so that it could be easily broken. This was inserted in a test-tube containing the gelatin medium. The latter was stopped up with cotton wool in the usual way with such experiments, and then sterilised at a temperature of about 130° C. under pressure for about thirty minutes. Controls without radium were also at various times thus similarly sterilised.

When the gelatin had stood for some time and become settled, the fine end of the tube containing the radium salt was broken, from outside, without opening the test-tube, by means of a wire hook in a side tube.

The salt, which in this particular experiment consisted of $2\frac{1}{2}$ milligrams of radium bromide, was thus allowed to drop upon the surface of the gelatin.

After twenty-four hours or so in the case of the bromide, and about three or four days in that of the chloride, a peculiar culture-like growth appeared on the surface, and gradually made its way downwards, until after a fortnight, in some cases, it had grown fully a centimetre beneath the surface.

If the medium was sterilised several times before the radium was dropped on it, so that its colour was altered, probably by the inversion of the sugar, the growth was greatly retarded, and was confined chiefly to the surface.

It was found that plane polarised light, when transmitted through the tube at right angles to its axis, was rotated left-handedly in that part of the gelatin containing the growth, and in that part alone.

The controls showed no contamination whatever, and no rotation. The test-tubes were opened and microscopic slides examined under a twelfth power. They presented the appearance shown in Fig. 1. At first sight these seemed to be microbes, but as they did not give subcultures when inoculated in fresh media they could scarcely be bacteria. The progress of any of the subcultures after a month was extremely small, and certainly

too small for a bacterial growth. It was not at all obvious how bacteria could have remained in one set of tubes and not in the other, unless the radium salt itself acted as a shield, so to speak, for any spores which may originally have become mixed with the salt, perhaps during its manufacture, and when embedded in it could resist even the severe process of sterilisation to which it was submitted.

On heating the culture and re-sterilising the medium, the bacterial-like forms completely disappeared; but only temporarily, for after some days they were again visible when examined in a microscopic slide. Nay, more, they disappeared in the slides when these were exposed to diffused daylight for some hours, but reappeared again after a few days when kept in the dark. Thus it seems quite conclusive that whatever they may be, their presence is at any rate due to the spontaneous action of the radium salt upon the culture medium, and not alone to the influence of anything which previously existed therein.

When washed they are found to be soluble in warm water, and however much they may resemble microbes,

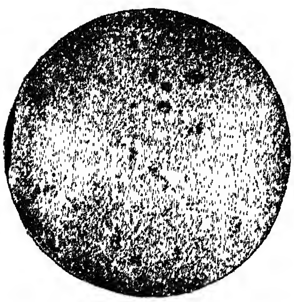

FIG. 1.

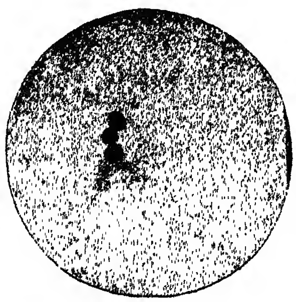

FIG. 2.

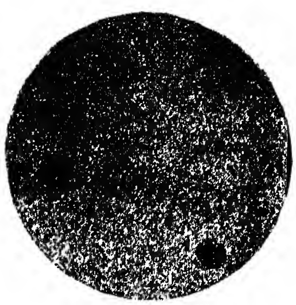

FIG. 3.

they cannot for this reason be identified with them, as also for the fact that they do not give subcultures as bacteria should.

Prof. Sims Woodhead has very kindly opened some of the test-tubes and examined them from the bacteriological point of view. His observations fully confirm my own. He assures me that they are not bacteria, and suggests that they might possibly be crystals. They are, at any rate, not contaminations.

I have tried to identify them with many crystalline bodies, and the nearest approximation to this form appears to be that of the crystals of calcium carbonate, but these are many times larger, and, in fact, of a different order of magnitude altogether, being visible under comparatively low powers; and are, moreover, insoluble in water.

A careful and prolonged examination of their structure, behaviour, and development leaves little doubt in my mind that they are highly organised bodies, although not bacteria.

Unfortunately the quantity is so very minute that a chemical analysis of their composition is extremely difficult. The amount of salt in the first instance is so small, and the number of aggregates, or whatever they may be, thus produced perhaps still smaller.

The most effective method of studying their properties, from the physicist's point of view, is that of long and, so far as possible, continual observation, a method similar to that which the astronomer is bound to adopt in his study of bodies over which he has not the control to deal with as he pleases.

From the accompanying photographs it will be observed that they are not all of the same size; they range from about 0·3 μ to the minutest specks; they are mostly, if not altogether, all of the same shape, and show distinct signs of growth; the larger ones appear to have sprung from smaller forms, and these in turn from still smaller ones, and they have all probably arisen in some way from the invisible particles of radium.

Fig. 2 distinctly shows the existence of nuclei in the larger and more highly developed forms, whilst Fig. 3 reveals, though indistinctly, what is their most remarkable property of all, and that is their subdivision when a certain size is reached. They do not grow beyond this size, but subdivide.

These photographs, together with the numerous results of eye observations, which indicate that a continuous growth and development take place, followed by segregation, leave little doubt that whilst on the one hand they cannot be said to be bacteria, they cannot be regarded as crystals either in the sense of being merely aggregates of symmetrically arranged groups of molecules, which crystals are supposed to be. The stoppage of growth at a particular stage of development is a clear indication of a continuous adjustment of internal to external relations, and thus suggests vitality.

They are clearly something more than mere aggregates in so far as they are not merely capable of growth, but also of subdivision, possibly of reproduction, and certainly of decay.

The subcultures do show, however slightly, some indication of growth after four or five weeks, although that growth is, I understand, too small for a bacterial subculture. Moreover, when examined in the polariscope they have not been found to yield the characteristic figures and changes of colour which crystals generally give.

Thus for these reasons I have been led to regard them as colloidal rather than as crystalline bodies, and probably more of the nature of "dynamical aggregates" than of "static aggregates," of which crystals are composed.

There appears to be a tendency amongst text-book writers to classify minute bodies which are not bacteria as crystals, but really without sufficient reason, and as these bodies cannot be identified with microbes, on the one hand, nor with crystals on the other, I have ventured, for convenience, in order to distinguish them from either of these, to give them a new name, *Radiobes*, which might, on the whole, be more appropriate as indicating their resemblance to microbes, as well as their distinct nature and origin.

Some slightly radio-active bodies appear also to produce these effects after many weeks.

A more detailed account of these experiments will be published shortly. This note merely contains some of the principal points so far observed.

I have to thank Mr. W. Mitchell, who sterilised the tubes, for the assistance he has rendered in these experiments.

JOHN BUTLER BURKE.

Cavendish Laboratory, Cambridge, May 10.

The Consolidation of the Earth.

THERE are several points in Dr. See's last letter (NATURE, May 11) calling for remark from the geological point of view.

(1) The effect of (hydrostatic) pressure at depths tends not to liquefaction (as in the case of the ice of a glacier) but to promote crystallisation, the condition of the greatest density of mineral matter, as I showed years ago in my little work on metamorphism in discussing the relation of the crystalline to the vitreous states. It is here that the importance of "solid-liquid critical state" comes in.

(2) We have no right to assume the existence at any stage of the history of our planet of a mere molten ball radiating heat directly into cold space, since in that "pre-oceanic stage" it was surrounded by a non-conduct-

ing mantle or "jacket" of such enormous density and altitude as to contain (as its main constituents) (*a*) the greater part of the water of the present hydrosphere in the vapour state; (*b*) the CO_2 locked up in the limestones and other carbonates of the lithosphere, as well as that represented by the coal and the living vegetation of the globe; (*c*) the hydrocarbons possibly represented by Archæan graphite, together with (*d*) the halogens (if atomic evolution had reached that stage), including the Cl_2 of the 73 per cent. of the NaCl of the salts of the present ocean. It is conceivable that a vast convection system existed, as the outer zones of the primordial atmosphere underwent cooling with consequent condensation, and descended towards the molten globe; but there could scarcely be contact generally between such cooler portions and the heated molten mass. The conditions would be rather such as are partly illustrated by what a student of physics is familiar with as the "spheroidal state" of a liquid floating on a cushion of steam above a hot plate of metal. Under the enormous pressure prevailing at the surface of the globe in that pre-oceanic stage of its history great quantities of superheated steam and other gases must have been mechanically included, and in some cases, perhaps, occluded, in the hot *crust* in the inceptive stages of its development by congelation; and in such circumstances, as I suggested seventeen years ago, superheated water in traces would probably enter into the composition of such silicates as *hornblende* and *mica,* the two most characteristic of the minerals of the heavier metals of the Archæan gneisses and schists. A year or two later that hypothesis received demonstration from the splendid work of de Kroustchoff (see NATURE, vol. xliii. p. 545, also *Bulletin de l'Académie des Sciences de St. Petersbourg,* tome xiii., "Über künstliche Hornblende," by K. von Chrustschoff). So, I take it, we can understand how such a crust could float on a magma of molten rock material, just as air-charged fragments of pumice or of charcoal float on water, yet sink quickly to the bottom under the exhausted receiver of an air-pump; or as even a coil of platinum foil (sp. gr. 21·5) can be made to float in water inside a good air pump, as it is pontooned by innumerable bubbles of distended atmospheric gases previously condensed upon its surface; or, again, as masses of lava slag of large dimensions are seen to float for a time upon the vast lake of liquid rock material in the crater of Kilauea. With tidal action in the magma greater when the moon was nearer the earth than at present, such a thin crust would easily undergo disruption, while portions of it would float off and be engulfed in the magma. This view, which I propounded some seventeen years ago, had been anticipated partly by Zöllner, and was adopted by the distinguished American geologist, Dr. A. C. Lawson, to explain the phenomena presented by the enormous inclusions of more basic rock masses in the gneiss of the Rainy Lake region, which excited great interest among our leading British geologists at the International Geological Congress in London in 1888, though it seems at the time to have been very imperfectly perceived by most of them. So far the evidence we have goes to support Dr. See's contention that the descent of such masses into the magma would be arrested long before they even approached the centre of the sphere; but one feels great difficulty in following his argument based on "Laplace's law," for reasons given in my former letter (NATURE, May 4).

By a slip I wrote, it appears, "impossibility" for possibility in the top line of p. 8 in my last letter.

Bishop's Stortford, May 17. A. IRVING.

The Spirit-level as a Seismoscope.

A MISCONCEPTION seems to prevail among seismologists as to the behaviour of a spirit-level. A displacement of the bubble is regarded as conclusive evidence of the tilting of the instrument. It should be pointed out, however, that this is far from being the case. For a second cause, equally effective in producing displacement of the bubble, is a horizontal acceleration of the instrument in the direction of the tube. The position of the bubble should be taken as indicating, not the normal statical vertical, but the dynamical residual vertical obtained by subtracting the acceleration of the instrument (as a vector) from that of gravity. (I disregard, in this statement, the slight lag due to viscosity.)

A couple of simple experiments, serving to emphasise this, may be suggested. A spirit-level is suspended in a horizontal position by two equal strings attached one to each end. In one case the strings hang vertically from two hooks; in the other case they are attached both to one hook. If the level is set swinging in the plane of the strings, then in the *first* case the bubble will be found to have an oscillatory movement relatively to the tube, the tube having linear acceleration but no tilting movement. In the second case the tube has both movements, but their effects exactly neutralise each other, and the bubble remains stationary in the tube. The expert waiter (may it be added?) who hurries about with plates of soup has a very effective empirical knowledge of this last case of compensation.

The motion of the bubble of a level has been brought forward as evidence in favour of the undulatory character of the disturbance producing the motion; but if the above suggestions are to be accepted, the motion might as reasonably be urged as evidence of a horizontal disturbance; the truth being that the instrument is sensitive to both disturbances, and is quite ineffective as a means of discriminating between them.

The evidence referred to is contained in the British Association report, 1902 (seismological committee report, p. 72). The view finds acceptance in some recent and authoritative works,[1] and seems, so far, to have passed unchallenged. G. T. BENNETT.

Emmanuel College, Cambridge.

A Feather-like Form of Frost.

THE accompanying photograph shows a form of frost not, I believe, usually seen except at a comparatively high altitude and unsheltered position. This photograph was

FIG. 1.—Frost "feathers" on windward side of rock.

taken on April 22 near the summit of Carnedd Llewelyn, N. Wales (3484 feet above sea-level). These delicate frost "feathers" appear gradually to grow outwards from the rock face on the windward side, and the delicacy of their form is, no doubt, modified in some degree with the varying rate of the wind and the temperature. I have found, in the same district, these "feathers" 9 inches from root to tip; those shown are about 6 inches long. They form a comparatively solid mass where they touch, but the tips keep distinct, and the whole mass is in reality very brittle, and easily breaks up into small pieces.

H. M. WARNER.

THE EVOLUTION OF ENGRAVING IN THE STONE AGE.

WE have at various times directed the attention of our readers to this interesting subject, but new discoveries are continually being made. M. Ed. Piette, whose name is so well known in connection with his investigation of the famous cave of Mas-d'Azil, has given in *l'Anthropologie* (xv., 1904, p. 129) a classification of the deposits formed in caves during the age of the reindeer; starting as a geologist, he was firmly impressed with the fact that stratigraphy is at the root of fruitful advance in prehistory, and this end he has kept steadily in view. He gives the following table of relative chronology of the epochs which form part of the age of the reindeer:—

Epochs of Lartet and Christy	Epochs of G. de Mortillet	Epochs of E. Piette
Madelaine and	Magdalénienne	Gourdanienne
Laugerie-haute	Solutréenne	Papalienne
Moustier	Moustérienne	Mostérienne

The following is his cultural sequence, in which the epoch of Moustier does not take part, "as at that time the fine arts were not yet born":—

Age or series	Epoch or stage	Layer
Glyptic	Of engraving (Gourdanienne)	Of engravings and harpoons of reindeer antler
		Of engravings without harpoons or with very few harpoons
		Of engravings with cut-out contours
	Of sculpture (Papalienne)	Of sculptures in low relief
		Of sculptures in the round

The sculptors in the round used their flint tools for many purposes, including carving, chiselling, scraping, engraving, and burnishing; they certainly sketched their statuettes before modelling them, and they polished them. The sculptors in low relief scraped and burnished. Their works were not child's play, but the product of a real artistic sense. They studied and drew heads, limbs, and feet (Fig. 1). The sculptors in the round figured the flayed animal and even the skeleton. When mammoth ivory became rare reindeer antlers were employed for carving, and this appears to have led the way to the next artistic developments.

Many of the figures in this copiously illustrated paper are from the layer of sculptures in low relief; it was in this layer that several pieces were found decorated with circles and bold spirals (Fig. 2). At first these designs were carved deeply, they gradually became less deep, until in the Gourdanienne epoch they were merely lines. M. Piette believes the spirals were symbolic, and suggests that they had reference to snakes. Plant forms were rarely drawn, and of the very numerous animals engraved by far the most frequent were those upon the flesh of which the men fed.

As the relief in the designs became less and less, the artist had to employ the graver. At the end of the Papalienne epoch the artists undertook to execute very low reliefs on plates of bone not more than two millimetres in thickness. They made silhouettes, modelling the contours on both sides; but the great difficulty of carving such thin objects soon led to its abandonment. They replaced this style by cutting out contours and engraving the surface. This technique was common in the region of the Pyrenees, but rare to the north of the Garonne; being a transitional form it did not last long, whereas sculptures in low relief persisted into later layers.

At first, following the traditions of the sculptor, the engraver represented isolated animals, but the artists of Laugerie-basse appear to have been the earliest to design groups (Fig. 3). In the upper layers signs are engraved which M. Piette considers to be of the nature of inscriptions.

Thanks to the rigid stratigraphical method employed by M. Piette, he has been enabled to upset the

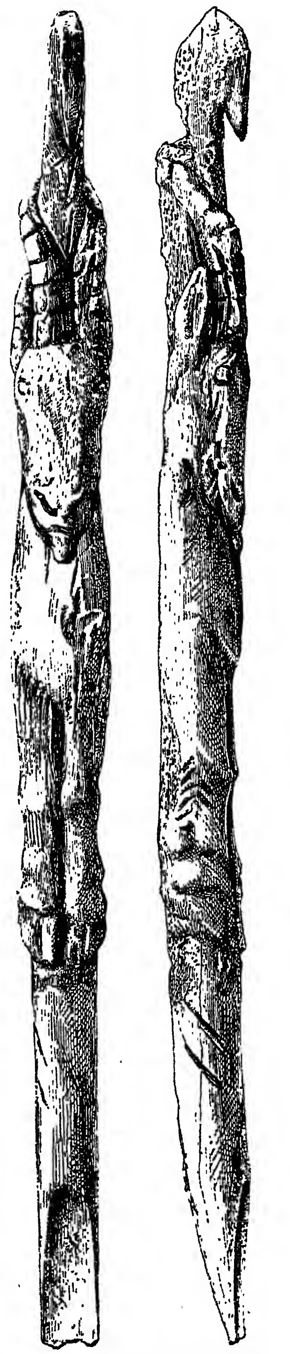

FIG. 1.—Bone Throwing-stick (Mas-d'Azil). Layer of sculptures in the round. Less than natural size.

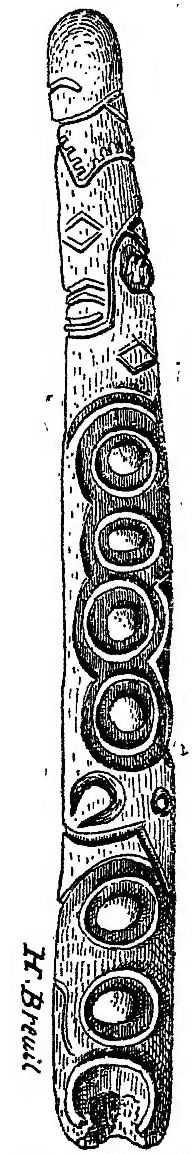

FIG. 2.—Portion of reindeer antler decorated with circles and other signs (Lourdes). Layer of sculptures in low relief.

a priori argument that sculpture was a later form of pictorial art than engraving, and has established that the reverse is the case.

In a subsequent paper, entitled "Les Écritures de

l'Age glyptique" (tome xvi., 1905, p. 1), M. Piette claims to have discovered "inscriptions composed of characters forming a primitive writing," all of which are from the layer of sculptures in low relief, and consequently from the earlier glyptic epoch. The first specimen figured by the author is that reproduced here as Fig. 2. First of all one must point out that only one side of this rod of bone is figured, but before the design can be understood it will be necessary to know what the whole design looks like. The author says, "The circle with central prominence appears to be a simplification of the circle with radiating centre which evidently signifies the sun or solar god. The rays have been suppressed in order to write the sign more quickly"; he then briefly gives the distribution of similar markings in prehistoric Europe and in Egypt. The lozenge is stated to be "certainly a symbol," and other signs are similarly believed to be symbols or hieroglyphs. "The spiral," for example, "has held a large place in primitive symbolism." This is possibly true, but spirals may mean many things in the art of existing backward peoples, and may be conventional symbols or more or less realistic representations; but it is extremely hazardous to make guesses as to what any given spiral may be intended to represent; the probability is that all such guesses will be incorrect, and the same remark applies to other elementary designs. Several spirals and concentric circles are figured by the author in juxtaposition, and the evidence seems to point to the conclusion that here, as in so many other instances from various parts of the world, the concentric circle or oval is a simplification of the spiral; if this be so, the theory that the concentric circles are degenerate rayed circles, *i.e.* suns, falls to the ground. The bold decoration on these bone objects in all probability had a meaning. Some of the designs may have been symbols; but, surely, it is somewhat far-fetched to describe them as hieroglyphs, and we cannot follow the author when he states (as he does in a letter to the editor), "According to me this inscription (Fig. 2) is the glorification of light."

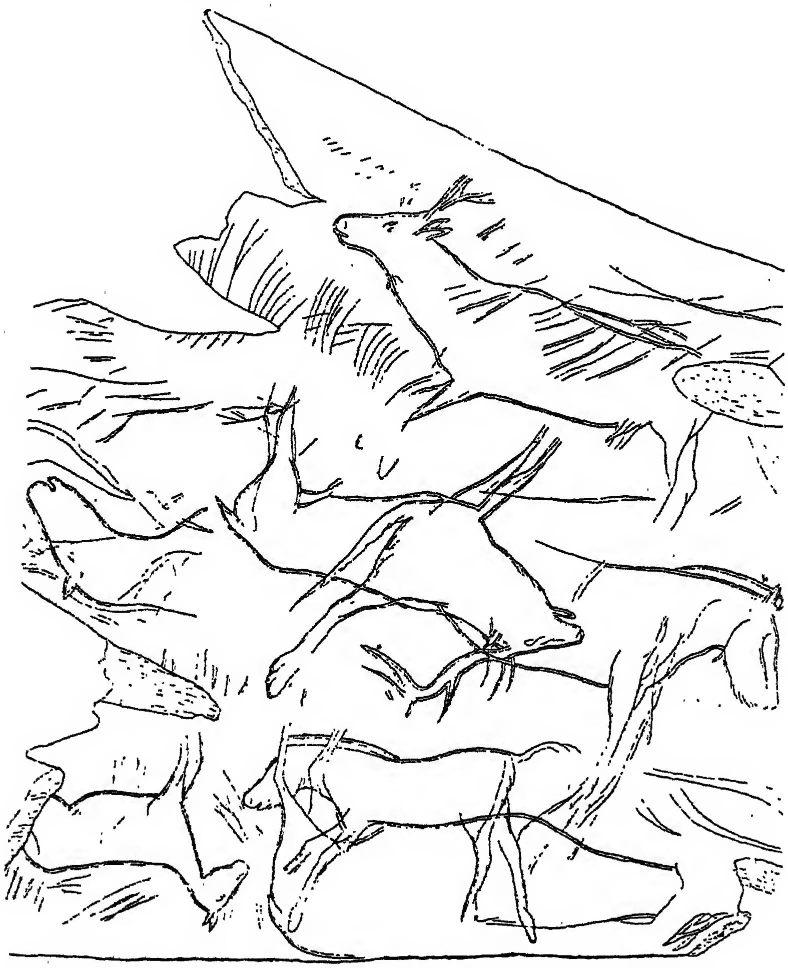

FIG. 3.—Engraving on bone (Lorthet). Layer of engravings without harpoons.

M. Piette also directs attention to certain linear markings on bones from various sites of the reindeer age. These he boldly claims to be true linear scripts, and suggests that the writings of la Madeleine and Rochebertier were continued into the linear script of Abydos without undergoing much change.

Archæologists are deeply indebted to M. Piette for the thoroughness with which he has carried out his investigations, and we must not unfairly criticise him if that enthusiasm which has carried him through his labours sometimes runs away with his more dispassionate judgment. He is probably quite correct in believing that the decoration on the bone objects he has discovered has a meaning, but judging from our experience of the decorative art of existing primitive peoples it is extremely improbable that we shall ever be able to decipher its meaning or unravel its symbolism. More evidence is needed before we can pass judgment upon the supposed linear script. A. C. H.

THE NEW DIPLODOCUS SKELETON.

ON Friday, May 12, in the presence of a large and representative company, Lord Avebury, on behalf of his fellow trustees, received from Mr. Andrew Carnegie the gift of the full-sized model of the skeleton of the gigantic American dinosaur known as *Diplodocus carnegii*, which has been mounted in the reptile gallery of the Natural History Branch of the British Museum under the superintendence of Dr. Holland, of Pittsburg, who has charge of the original specimens on which the complete restoration is based. Although the gigantic four-footed dinosaurs constituting the group Sauropoda were first made known to the world on the evidence of detached bones and teeth described by Mantell (Pelorosaurus) and Owen (Cardiodon and Ceteosaurus), it has been reserved for American palæontologists, working in the rich Upper Jurassic beds of Wyoming and Colorado, to give to the world an adequate conception of the huge proportions and extraordinary form of these strange reptiles. Strangest of all is perhaps Diplodocus (so named on account of

the double chevron-bones, which were at first thought to be peculiar to this form, although now known to be common to the entire group), which appears to be distinguished from all its relatives by the weakness of its dentition, the teeth being reduced to a small number, of the size and form of lead pencils, confined to the front of the jaws. Another remarkable feature, which may, however, have been common to other members of the group, is the position of the nasal aperture at the top of the skull, this being not improbably indicative of partially aquatic habits, an inference confirmed by the nature of the dentition of Diplodocus, which can scarcely have been adapted for anything else than a diet of soft and luscious water-plants.

Diplodocus was apparently one of the largest representatives of the group, the length of the skeleton, as mounted, being about 75 feet, while if the vertebral column were placed in a straight line the length would be some 10 feet more. The height at the shoulder is about 14 feet. The only rival to such bulk at the present day is presented by the skeleton of Sibbald's rorqual. That such a monster should have a skull considerably smaller than that of a large crocodile is one of the most remarkable facts made apparent by this restoration; while scarcely less noteworthy are the extreme elongation of the neck and tail (the latter for several feet of its length being comparable to a huge whip-lash), and the shortness of the trunk. With the exception of the bones regarded as the clavicles, of which only one original specimen was found, and the position of which in the skeleton may be doubtful, there is full authority for every bone in the model; so that we are now practically as well acquainted with the osteology of these monsters as we are with that of crocodiles.

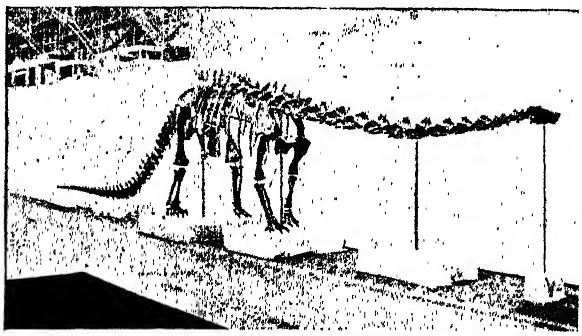

FIG. 1.—Restored Model of the Skeleton of *Diplodocus carnegii* as originally set up in the Museum at Pittsburg. From a photograph presented by Dr. Holland to the British Museum.

Mr. Carnegie's gift, which is due to the initiation of the King, is not only of immense value and interest to the man of science, but will likewise prove a great attraction to the ordinary visitor to the Museum. It is almost an appalling thought that the skeleton of a creature which lived at least several million years ago should have come down in such marvellous preservation to our own day.

THE MASAI OF EAST AFRICA.[1]

THE Masai (the word should be pronounced with a stress on the first syllable—Másai) were first distinguished and described as an East African people by the missionary Krapf, who, with Rebmann, was the discoverer of Mounts Kenia and Kilimanjaro. Krapf, who commenced the exploration of equatorial East Africa in 1848, had begun dimly to perceive the remarkable oneness in language of the Bantu tribes in the southern half of Africa from the Equator to Natal and Cape Colony, and he was therefore puzzled to find in the Masai a race intruding into Bantu East Africa which spoke a language absolutely different from the Bantu type.

At this period—let us say about 1850—the Masai had forced themselves on the attention of the Arab rulers of East Africa by their raids on the cattle of the Bantu tribes, raids which brought them occasionally to within sight of the island-town of Mombasa. In the 'fifties of the last century, nevertheless, the Masai had not established that reign of terror which during the 'sixties, 'seventies, and 'eighties did so much to obstruct the exploration of eastern equatorial Africa, and so long prevented the white man from travelling direct from the Mombasa coast to the eastern shores of the Victoria Nyanza. Therefore, in the 'fifties of the nineteenth century, Swahili, Arab or Baluch traders managed to reach the east and north-east coasts of the Victoria Nyanza from Mombasa or Lamu. The stories they told to Krapf and other missionaries gave to Europeans the first hint of the existence beyond the Masai of tribes allied in speech and physical characteristics and habits. During the 'seventies the Masai pushed their raids further and further south, until they were almost heard of—so to speak—in the regions immediately to the north of Lake Nyasa. In this direction they were ultimately checked by the sturdy resistance of the Bantu Hehe people, a vigorous race that long resisted German dominion in the same territory, a race made more warlike and coherent by a slight infusion of Zulu immigrants from the south. To the south-west the Masai were checked by the warlike Wagogo, to the west by the distantly allied tribes of Lumbwa and Ja-luo, and to the north by the Galas and Somalis. It is possible, however, that but for the eventual interposition of the European they might have

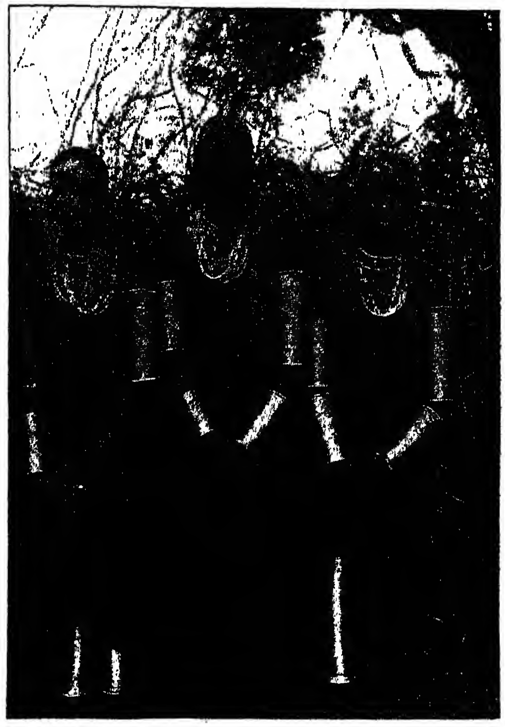

FIG. 1.—Masai girls, showing ornaments. From Hollis's "The Masai."

[1] "The Masai, their Language and Folklore." By A. C. Hollis. With an introduction by Sir Charles Elliot. Pp. xxviii+356. (Oxford: Clarendon Press, 1905.) Price 14s. net.

subdued the Bantu coast people and the Arab half-breeds to the shores of the Indian Ocean.

All observers of the Masai have noted their superiority in physical appearance to the pure-blooded negro. There has evidently been a good deal of intermixture, especially during the last three decades, with women of Bantu race, and the original Masai stock itself is only one of the many hybrids between the Caucasian and the negro; but still the average man or woman of Masai race is a negroid rather than a negro, with a skin of coppery-brown, not black,[1] with a more defined bridge to the nose and a better developed chin than the ordinary negro possesses. They are, however, far more negro in appearance than, for example, the Hamitic (Hima) aristocracy of the lands lying to the north, west and south of the Victoria Nyanza; yet they retain a larger infusion of Caucasian blood (due, of course, to Hamitic intermixture) than the pure type of Nilotic negro, to which in other respects they are nearest allied in origin, language, and, above all, in habits and customs.

FIG. 2.—Masai warriors of various "ages" and "districts," each with the shield of his "age" and "district." From Hollis's "The Masai."

Now that our knowledge of eastern equatorial Africa is so extensive, we realise that the Masai are no isolated phenomenon in racial distribution, but are simply a southward extension of the Nilotic peoples. They probably originated several hundred years ago in the northern part of the present Uganda Protectorate, in the mountainous country between the present abode of the Lotuka tribe (the nearest allies of the Masai in language) and the Turkana peoples to the east. In this region they were simply one of the many blends between the Hamitic (Gala) invaders of equatorial Africa and the Nile negroes. The writer of this review, in his work on the Uganda Protectorate (p. 841), has computed that the proportion of Caucasian intermixture in the case of the Masai is from one-quarter to one-eighth. Their language, which for classification may be grouped with the Lotuka, Elgumi or Wamia, Bari (on the White Nile), Karamojo, and Turkana, is, together with the nearly allied group of the Nandi-Dorobo, distinctly, though distantly, related to the well marked Nilotic family of negro languages which includes the Dinka, Shiluk, Dyur, Acholi, &c., and links on to the negro languages stretching away to Wadai and Lake Chad. In the Masai language, as in the kindred tongues of the Masai group, there is distinct evidence of Somali or Gala influence. This may be due to the ancient intermixture of blood between the Gala and the Nilotic negro which formed the Masai, and also to the contiguity of the Masai in some of their wanderings with outlying groups of Hamitic people.

For the first time the civilised world has been presented with an authoritative work on the Masai language, customs, and folklore, by Mr. A. C. Hollis, of the British East Africa Protectorate. Nothing of the kind worth serious notice has appeared since the works of Krapf and Erhardt. Though a Masai dictionary remains to be composed which shall give a full vocabulary of this interesting language, the book under review can scarcely be bettered in fulness or correctness as a grammatical study. Equally admirable is the collection of Masai legends. These are not given in the form of generalised "stories" with a Hans Andersen flavour; but the original is first of all presented in the Masai with an interlinear translation, and then follows a correct but more readable version in colloquial English. Of necessity, a work like this is more interesting to students than to the general public (though it is admirably illustrated with appropriate photographs). But for the students of African ethnology and languages it is a work of permanent value; it is *the* authoritative study of the Masai people; and it is satisfactory to record that the author confines himself mainly to facts and not to theories, and that Sir Charles Eliot in his introduction does not trace the origin of the Masai to the ten lost tribes of Israel. A recrudescence of this irritating mania having recently appeared amongst German writers on Africa who ought to have known better, it is a relief to find that English authorities on African questions can still retain their sanity on the subject of the proper place in history and ethnology of that mixed Armenian, Dravidian, and Semitic people which we call by the racial name of Jew.

H. H. JOHNSTON.

[1] Owing to their habit of smearing their bodies with a red clay, they strike the casual observer as being a red-skinned rather than a brown race.

NOTES.

THE anniversary dinner of the Royal Geographical Society on Monday was really a complimentary banquet to Sir Clements Markham, the popular and active president of the society, who has just retired from office after twelve years of zealous service. During this period Sir Clements Markham has watched over the affairs of the society, and has guarded the interests of geography, with a devotion

and untiring energy which it is easier to admire than to emulate. But his influence has not only been exerted while directing the affairs of the society as president, for he was honorary secretary of the society from 1863 to 1888, and the Founder's medal awarded to him upon his retirement was a mark of appreciation of his work for the promotion of geography, both in connection with the society and otherwise. It is, indeed, difficult to think of the Royal Geographical Society apart from the personality of Sir Clements Markham, for in all the affairs of the society he has long been ubiquitous. Wherever and whenever geographical interests could be advanced, he has championed them with a strength of view and courage of conviction which have commanded the admiration even of those who have differed from him. He has always been jealous of the honour of his charge; and only those who have been closely associated with him can appreciate adequately how carefully he has cherished the society's welfare. At the banquet on Monday, the chairman, Sir George D. T. Goldie, who has succeeded Sir Clements Markham in the presidential chair, referred in eloquent terms to Sir Clements' work as explorer and author, and his great achievement in the introduction of the cultivation of the Cinchona plant from South America into India. Messages of regret upon the retirement of Sir Clements Markham were read from the King and the Prince of Wales. After Sir Clements had replied to the toast of his health, a testimonial was presented to him from the relatives of the officers and members of the scientific staff of the *Discovery* in recognition of his courtesy in keeping up communication with them. This souvenir consisted of a reproduction of the Cashel cup, and bore a suitable inscription. There was also a gold pin studded with jewels for Lady Markham.

MM. METSCHNIKOFF and ROUX, who have recently shown that syphilis is inoculable on the higher apes, at a meeting of the French Academy of Medicine on May 16 announced that they have at last detected the microorganism of this disease. The microbe appears to be a long, delicate, spirillar form, difficult to observe, and readily destroyed by any manipulations. It seems to have been seen first by MM. Bordet and Gengou, of the Pasteur Institute, three years ago, and subsequently by Herren Schaudinn and Hoffmann, by whom it was named *Spirochaete pallida*. It measures 4–14 μ in length by 1 μ in breadth, and though resembling similar organisms in mucus, &c., is readily distinguished from these. The spirochæte has been found in four out of six human cases of the disease, and also in the inoculated monkeys, and Dr. Levaditi also exhibited preparations of it obtained from a child suffering from hereditary syphilis.

THE Royal Medical and Chirurgical Society celebrated the centenary of its foundation by a dinner on May 22, which was attended by the Prince of Wales and a large and distinguished company, the president, Sir Douglas Powell, Bart., presiding. In responding to the loyal toasts, the Prince of Wales (who is an honorary Fellow of the Society) expressed his pleasure at being present. He regarded his position as president of King Edward's Hospital Fund as a precious trust, and he watched with keen interest and satisfaction the gradual but steady development of medical science. He congratulated the Society on celebrating the 100th anniversary of its foundation, a period which had been prolific in advances in medicine and surgery. Physiology had become established as a precise branch of learning; bacteriology had laid bare the foundations of disease; antiseptics and the clinical thermometer had been invented; our hospitals had become institutions in which the most beneficent treatment is carried out with scientific thoroughness; and in the sphere of public hygiene nothing short of a revolution had been effected. Among the guests were the Duke of Northumberland, Lord Strathcona, Lord Alverstone, Sir W. Huggins, P.R.S., Mr. John Tweedy, P.R.C.S., Surgeon-General Keogh, Prof. Ray Lankester, Sir W. Ramsay, Sir F. Treves, Sir P. Manson, Prof. Christian Bohr, Prof. Pierre Marie, and many others. Last night the Fellows and their friends and other guests were entertained at a soirée at the Natural History Museum. As a fitting supplement to the centenary festivities, it may be mentioned that the society recently invited delegates from the other medical societies to confer on the practicability of an amalgamation between the various societies and the foundation of an "Academy of Medicine," such as exists in Paris and other cities.

IN connection with the fiftieth anniversary of the Société des Sciences naturelles de Lucerne, which takes place this year, the Société helvétique des Sciences naturelles will hold its eighty-eighth annual meeting at Lucerne on September 10 to 13 inclusive. The business of the meeting will be carried on in seven sections, dealing respectively with mineralogy and geology, botany, zoology, chemistry, physics and mathematics, medicine, and civil engineering. Lectures to the general assemblies have been promised by Profs. F. Zschokke, A. Heim, and H. Bachmann. Five scientific societies will hold their annual meetings at Lucerne on the same occasion, namely, the Swiss societies of geology, botany, zoology, and chemistry, and the Zurich Physical Society. Full particulars can be obtained by writing to the president of the meeting, Dr. E. Schumacher-Kopp, Adligenschwylerstr., 24, Lucerne.

IN commemoration of the first admission of women to the full fellowship of the Linnean Society, a dinner was given to the lady fellows of the society on May 18, at the invitation of the treasurer, Mr. F. Crisp.

MR. A. HOWARD has been appointed by the Secretary of State for India economic botanist to the Imperial Department of Agriculture of India. He will be stationed at the experiment station at Pusa, Behar, Bengal.

A COURSE of instruction in oceanic research will be held at Bergen, during the university vacation, from August 8 to October 14. The course, as in previous years, will consist of lectures, practical instruction and assistance in laboratory work; excursions will also be made, during which the use of various appliances and instruments will be practically demonstrated. The work will be in charge of Dr. A. Appellöf, Dr. D. Damas, Dr. H. H. Gran, Mr. B. Helland-Hansen, Dr. Johan Hjort, and Mr. C. F. Kolderup. Further particulars can be obtained from the Oceanographical Institute of Bergen Museum, Bergen, Norway.

THE association which maintains an American woman's table in Dr. Dohrn's marine laboratory at Naples also offers at stated times a cash prize of 200*l.* for the best thesis presented by a woman of any nationality embodying original laboratory research. This prize was awarded at the annual meeting in Boston, on April 29, to Miss N. M. Stevens for a paper on the germ cells of *Aphis rosea* and *Aphis oenothera*. The theses offered in competition for the next prize should be presented to the executive committee of the association, and must be in the hands of the chairman of the committee on the prize, Mrs. Ellen H. Richards, Massachusetts Institute of

Technology, Boston, Mass., before December 31, 1906. The prize will be awarded at the annual meeting in April, 1907.

AT the meeting of the Pathological Society of London on May 16, Mr. C. Walker gave a demonstration which seems to solve the nature of the so-called "cancer bodies" (Ruffer's bodies) of malignant tumours, which have been believed by many to be parasitic protozoa. He showed specimens of the normal reproductive cells of the testis containing bodies which are apparently identical with the "cancer bodies," but are really the archoplastic vesicles of those cells.

IN the *Bulletin of the Johns Hopkins Hospital* for April (xvi., No. 169) the most interesting and important communication is by Dr. Clowes on the immunisation of mice against cancer. In certain mice which had been inoculated with mouse cancer, the disease underwent an unexpected and spontaneous retrogression, and it was found that the serum of these animals produced a marked curative effect on the cancerous tumours in other mice suffering from the disease.

DR. W. B. WHERRY records some interesting observations on the biology of the cholera spirillum (*Bull. Bureau of Gov. Laboratories, Manila*, No. 19), in which he shows that the slight variations in cultural and other characters so often met with in different strains of this micro-organism are largely due to slight differences in the culture media employed, particularly in their reaction, and suggestions are given for the more accurate preparation of standard media.

THE *Journal of the Royal Sanitary Institute* (xxvi., No. 4) contains a report of a discussion on the aërial dissemination of small-pox round small-pox hospitals, in the course of which Dr. H. E. Armstrong, Dr. T. M. Clayton, and others adduce a good deal of evidence against the commonly accepted view of the danger of aërial infection in the neighbourhood of such hospitals. Municipal milk depôts and milk sterilisation is the subject of another paper by Dr. G. F. McCleary.

DR. CHARLES CREIGHTON, who recently paid a special visit to India for the purpose of inquiring on the spot into some of the circumstances connected with the prevalence of plague, read a paper on this disease before the Society of Arts on May 18. Dr. Creighton first criticised the composition of the British Plague Commission of 1898, complaining that there was no epidemiologist upon it. He next gave a somewhat detailed account of the geographical distribution of plague, and directed attention to the difference of incidence of the disease in the villages of the district of Ratnagiri and those of the adjoining district of Satara. In the former all the buildings, roadways, &c., are of stone, and plague occurs little or not at all; in the latter the villages are plague-stricken, and the crowded dwellings are of mud, the floors, &c., being saturated with offal. Dr. Creighton believes that crowded sites too long inhabited and without drainage are the cause of the trouble, which is explicable on the laws of soil-infection enunciated by Pettenkofer and his school.

A PRICED catalogue of pinned specimens of Lepidoptera, issued by Mr. H. Fruhstorfer, of Turmstrasse, Berlin, from whom we have received a copy, should prove useful to collectors.

AMONG our weekly budget are included three papers on North American zoology. In the first, from the *Bulletin of the Brockly Institute* (vol. i., No. 5), published by the Macmillan Company, Dr. J. A. Allan gives a list of mammals from Beaver county, Utah, several of which are described as new. The mammals of this elevated region are stated to differ considerably from their representatives in the adjacent foot-hills. In No. 6 of the same serial Mr. C. Schæfer describes new American beetles, and in the third paper (from the *Proceedings of the U.S. Museum*) Mr. W. D. Kearfoot diagnoses new tortricine moths from Carolina.

IN the April issue (vol. i., part iv.) of the *Records of the Albany Museum* Dr. R. Broom discusses the proper signification of the Owenian term "Anomodontia," and comes to the conclusion that it is applicable only to the dicynodonts. He also describes certain new fossil reptiles from Aliwal North, and contributes some important notes on the localities of type specimens of other South African reptiles, especially those in the British Museum. In the course of these remarks, it is pointed out that Anthodon is of Wealden age, and probably, therefore, a dinosaur instead of a pariasaurian, and that the limb-bones described by Owen as Platypodosaurus are almost certainly referable to Udenodon.

IN the issue of *Biologisches Centralblatt* of May 1 the Rev. Father Wasmann brings to a close his important series of articles as to the origin of slavery among ants, and formulates the conclusions at which he has arrived, which are too long to be recapitulated in our columns at length. It may be mentioned, however, that, in the author's opinion, this system of slavery had independent origins at different dates respectively in the formicine and the myrmecine sections of the ant family, and that it has also been independently acquired in different genera and species of these two subfamilies at different times. In general, it seems to have been of later origin in the Formicinæ than in the Myrmecinæ. Moreover, the phenomenon affords confirmation of the biological doctrine that the ontogeny of a group constitutes a brief recapitulation of its phylogeny. In another article in the same issue Dr. O. Zacharias emphasises the importance of modern methods of studying "hydrobiology" in relation to fish-culture and fisheries.

PART iii. of vol. xlvii. of the quarterly issue of *Smithsonian Miscellaneous Contributions* contains an article by Mr. C. D. Sherborn on the species of birds described as new in Vroeg's catalogue, published in 1764. P. S. Pallas is believed to be the real author of the names. The only copy of this work that has come under the author's notice is in the library of the Linnean Society, where it might have been left in well merited obscurity. Social spiders (*Stegodyphus sarasinorum*) form the subject of another article, by Mr. N. S. Jambunathan, in the same serial. The spiders of this species, which was discovered by the author at Saidapet, Madras, in 1898, live in a sponge-like nest formed of branching net-work with communicating canals and a number of external openings. These nests, which may be attached either to the tips of branches of trees or to leaves of the prickly pear, are ashy-grey in colour, and constructed of leaves and refuse from the spiders' food. Externally is a coat of stout sticky threads of the same colour as the spiders themselves, and sheet-like webs spread in all directions from the nests. Five or six nests are often found together, each of which may be the home of from 40 to 100 spiders, usually in the proportion of seven males to one female. A number of spiders will cooperate to overpower a single large insect.

DURING the last few days paragraphs have appeared in the newspapers stating that a plague of flies has invaded Cardiff Docks, causing much inconvenience. The flies are said to have made their appearance with a southerly wind on Sunday, May 14. Mr. Ernest E. Austen, of the British Museum (Natural History), informs us that specimens forwarded to the museum show that the trouble has been caused by the fly known as *Dilophus febrilis*, Linn., a very common British species of the family Bibionidæ, met with from April to September, but especially abundant in May. In colour the flies are black, with a shining thorax, and measure about $5\frac{1}{2}$ millimetres, or rather less than a quarter of an inch, in length. As in all Bibionidæ, the males are distinguished from the females by the large size of the head, which in the former sex appears from above to be entirely composed of the eyes. Of five specimens sent to the British Museum, all were males. *Dilophus febrilis* breeds in horse and cattle droppings, in which the larvæ—white footless grubs measuring half an inch in length, with a dark brown head capsule at the anterior extremity—are found in small masses. This fly is quite incapable of biting, as are also all the other species of the same family, so far as at present known, though the possession of an elongated proboscis by two Mexican representatives of the genus Plecia suggests that there may be forms that suck blood. The occasional occurrence of Bibionidæ and other Diptera in immense numbers is well known, and notes on the subject have already appeared in these columns (*cf.* NATURE, vol. xlviii., 1893, pp. 103, 127, 176). With regard to *Dilophus febrilis*, Mr. J. W. Douglas, writing in the *Entomologist's Monthly Magazine* for 1880 (p. 142), describes a swarm of this species at sea off the Norfolk coast on September 2 of that year. It is stated that the air was obscured by the flies as by a cloud, and that a schooner sailing at about a cable's length from the shore was so covered with them that for five hours persons were unable to remain on deck; the air cleared at about 4 p.m. The cause of these phenomenal swarms is still uncertain, but it is probably to be found in exceptionally favourable climatic conditions, which, by accelerating the growth of the larvæ and shortening the pupal stage, cause myriads of flies to appear at practically the same time.

IN the *Biological Bulletin* (February) Mr. R. S. Lillie discusses the conditions determining the disposition of the chromatic filaments and chromosomes in mitosis, and advances a physicochemical theory, based upon mutual repulsions of the particles of a colloid solution, to explain the sequence of the stages in nuclear division.

A REVISION by Mr. B. Hayata of the Euphorbiaceæ and Buxaceæ of Japan, as represented in the herbarium of the University of Tokio, forms article iii. in vol. xx. of the Journal of the College of Science in that university. The number of genera is limited to twenty-four under Euphorbiaceæ and two under Buxaceæ, and seven new species are recorded. The author has provided figures of the flowers for most of the species.

A BRIEF survey of the progress of the Nilambur Teak Plantations, Madras, from its inception by Mr. Conolly in 1840 to its present condition, when the receipts more than balance the cost, is contributed by Mr. R. McIntosh to the *Indian Forester* (March). The harvest time is still thirty-five years ahead, when the fellings are expected to produce a revenue of 40,000*l*. a year. The difficulty experienced at first in getting the seed to germinate was overcome by soaking the seeds before planting, and by keeping the soil thoroughly moist after planting. The teak forests of Burma form the subject of another article, in which Mr. R. S. Troup comes to the conclusion that useful as fire protection may be in most forests, annual burning in moist mixed forests of teak and bamboos is decidedly efficacious.

THE appearance of a *Nature-study Review*, edited and published by Mr. M. A. Bigelow in Lancaster, Pennsylvania, indicates that the subject is making progress in the United States. A discussion in the first number as to the scope of nature-study has led to a general expression of opinion that it differs from natural science in so far as it lacks the characteristic organisation of science, and that it should be confined to elementary schools; further articles on the subject appear in the March number, which is the second of a bi-monthly issue. Amongst the articles giving the experiences of teachers one by Dr. E. A. Bigelow directs attention to the convenience of putting up the salts required for plant food solutions in tabloid form.

IN *Spelunca* (*Bull. de la Soc. de Spéléologie*, tome v., Nos. 39 and 40) there are interesting articles on the caverns and subterranean water-courses of the Mendip Hills, by Mr. H. E. Balch, and on those of the Jura Mountains by M. E. Fournier.

MR. E. C. DAVEY, who in 1874 contributed to the *Transactions of the Newbury District Field Club* an essay on the sponge-gravel beds near Faringdon, with photographs of some of the fossil sponges, has revised and amplified his article under the title "The Neocomian Sponges, Bryozoa, Foraminifera, and other Fossils of the Sponge-gravel Beds at Little Coxwell, near Faringdon." This is now published by Messrs. Dulau and Co., price 5*s*. net, and it contains five photographic plates of sponges, Echini, and Foraminifera. The nomenclature of the sponges is revised in accordance with the researches of Dr. G. J. Hinde, but the author does not wholly agree with the determinations made by that palæontologist, and adds other species, one new species being figured and briefly described. Under the heading "Bivalves," the author includes brachiopods and lamellibranchs; he makes no reference to the occurrence of Belemnites, to which Mr. G. W. Lamplugh directed special attention in 1903 (*Geol. Mag.*, p. 32).

BASING his conclusions largely on the capacity of the cranium, but also taking into account other characters, Mr. A. da Costa Ferreira has attempted to dissect out, as it were, the probable racial constituents of the Portuguese, and has set forth his results in the *Bulletin de la Société d'Anthropologie de Paris* (5e. sér., tome v., p. 473). He finds a short, mesorhine dolichocephalic type with a small head which he thinks belongs to the Cro-Magnon race, and a tall, leptorhine dolichocephalic type with a large head. The mesaticephals are partly attributed to a brachycephalic mixture; those of short stature, leptorhine, and with a large head, are thought to belong to the race of Grenelle or to a Celtic invasion. The small headed, leptorhine mesaticephals are probably of Semitic origin, while the mesorhines may be of Berber extraction.

IN order to make more widely known and more easily accessible to American students the results of important researches on the Maya hieroglyphs, printed in the German language, the Peabody Museum Committee on Central American Research has begun a series of translations of which the first, on the representation of deities of the Maya manuscripts, by Dr. P. Schellhas, has been published as vol. iv., No. 1, of the *Papers of the Peabody*

Museum, Harvard University. In this valuable enumeration Dr. Schellhas is very careful not to theorise or to go beyond the warrant of the manuscripts themselves. In several cases he refers to diverse views concerning the names of the gods in question; but, as he truly observes, "these different opinions show on what uncertain grounds such attempts at interpretation stand, and that it is best to be satisfied with designating the deities by letters and collecting material for their purely descriptive designation. In vol. iii. of the same *Papers* are illustrated accounts of the Cahokia and surrounding mound groups, by Mr. D. I. Bushnell, and of the exploration of mounds in Coahoma, co. Mississippi, by C. Peabody. In vol. i. Mrs. Zelia Nuttall gives a very interesting account of a penitential rite of the ancient Mexicans mainly derived from Spanish sources. Blood was drawn from cuts in various parts of the body, including the tongue and ears; the rite of voluntarily drawing blood, principally from the ear, was a feature of every-day life in ancient Mexico, and was performed by young and old. It constituted an act of humility, thanksgiving, penitence, or propitiation.

THE Survey Department of Egypt has published an important paper on the rainfall of the Nile basin in 1904, by Captain H. G. Lyons, director-general of the service. Five years ago there were only six or eight places where the rainfall was being measured regularly; now, thanks chiefly to the efforts of Captain Lyons, there are more than forty, of which thirty-two lie to the south of Berber (lat. 18° N.). He points out that to understand the seasonal variation of the rainfall the relative positions of the equatorial low-pressure belt, and the high-pressure areas to the north and south of it at different seasons, must be taken into consideration. In the low-pressure area there is an ascensional movement of the air, so that its moisture is condensed to form clouds and rain. This ascensional movement depends upon the heating effect of the sun, and it is shown month by month how the low-pressure area varies with respect to the sun's position from south to north, and back to south again. The carefully prepared tables and diagrams show, as a general result, that the rainfall of 1904 in the Nile basin was below the average; in the equatorial regions it was somewhat deficient in the earlier part of the year, and above the average in the autumn.

A SOMEWHAT striking paper has been published by Prof. Ronald Ross, F.R.S., of Liverpool University, on verb functions, with notes on the solution of equations by operative division (*Proceedings of the Royal Irish Academy*, xxv., A, 3). The writer points out that whereas symbols such as f and ϕ are used to denote functions in general, no notation exists which can explicitly represent the operation of forming any *particular* function of any argument, apart from the argument itself, except in certain simple cases as exemplified by the prefixes log, sin, &c. The notation proposed by Prof. Ross meets this want. It depends on the use of a purely symbolical letter β to denote the *base* of a given operation, this symbol occurring in the "verb function" or operator. When this verb function operates on a subject x, it produces the result obtained by writing x for β in the operator. For example,

$$[\beta^{m/n}](ab)=(ab)^{m/n}, [\beta \log \beta - 1]x = x \log x - 1, [\epsilon^{\beta} \cos \beta]x = \epsilon^{x} \cos x,$$

and so on. Another peculiarity is the use of square brackets to enclose each separate operation, the necessity of which may be illustrated by the following example:—
$[(a+\beta)^2]x$ represents $(a+x)^2$, whereas

$$[a+\beta]^2x=[a+\beta][a+\beta]x=[a+\beta](a+x)=a+(a+x)=2a+x.$$

In connection with inverse operations, Prof. Ross introduces the notation of a double fraction or solidus line as a distinction from the ordinary division symbol; thus, according to his notation, we should have

$$\frac{1}{[a\beta^2+b\beta+c]}0 = -\frac{b \pm \sqrt{(b^2-4ac)}}{2a}$$

as the symbolical enunciation of the expressions for the roots of a quadratic equation.

THE peculiar magnetic properties of the so-called Heusler's bronzes, consisting of copper, manganese, and aluminium, are the subject of a paper by E. Take in the *Verhandlungen* of the German Physical Society (vol. vii., 133). The "transformation points" of a number of samples of the bronze were determined, as well as the effect of heating and re-heating upon them. The results are shown in a series of striking curves.

REFERENCE has already been made in these notes (NATURE, vol. lxx. p. 583) to the simple form of telescope pyrometer invented by M. Féry for measuring high temperatures. This instrument is now being sold by the Cambridge Scientific Instrument Co., Ltd., who have been appointed sole agents for its sale in the United Kingdom, the British colonies, and in the United States; it is made in two forms, a mirror pyrometer, recording temperatures between 500° C. and 1100° C., and a lens pyrometer, reading between 900° C. and 3500° C.

PROF. MOISSAN has published, in the form of a pamphlet having the title "La Chimie minérale, ses Relations avec les autres Sciences," an address delivered last September at the Congress of Arts and Sciences at St. Louis. Prof. Moissan, who by his own researches and those of his colleagues has so widely enlarged the domains of inorganic chemistry, whilst regretting that this branch of science is still systematically imperfect as compared with organic chemistry, emphasises the fact that during the past few years its study has again resumed a place of honour. This has been due largely to the discovery of the gases of the atmosphere, to research at high and low temperatures, the investigation of the rare earths, and to the increasing tendency to the fusion of chemical and physical methods. "Many important investigations still remain to be made in inorganic chemistry, but for success very refined methods and a high degree of accuracy will be required. Chemical research must acquire the precision of physics." Finally, it must be recognised that experiment is the sole guide to truth, and that Faraday's saying still holds true that chemistry is essentially an experimental science.

THE recent researches of M. Berthelot on the permeability of fused quartz vessels to gases at high temperatures have led him to study glass from the same point of view, with very interesting results. In many analytical processes, and more especially in the analysis of organic compounds, it is tacitly assumed that at temperatures below its melting point glass is impermeable to oxygen, nitrogen, and carbon monoxide and dioxide. In the current number of the *Comptes rendus*, M. Berthelot gives an account of some experiments on glass, the mode of working being the same as that used for the quartz tubes (see NATURE, April 13, p. 568) with the exception that the tubes were necessarily slowly cooled, and finds that at temperatures between 550° C. and 800° C. glass tubes are permeable to gases. He compares the passage of gases through slightly softened glass to the gaseous exchanges taking place at the ordinary temperature through the walls of indiarubber tubing, and emphasises the importance of this property of glass, hitherto unsuspected, in many chemical and physical investigations at high temperatures.

MESSRS. CROSBY LOCKWOOD AND SON will publish shortly a work on "Modern Lightning Conductors," by Mr. Killingworth Hedges, honorary secretary of the Lightning Research Committee.

AN appendix to Mr. R. L. Taylor's "Student's Chemistry" has been published by Mr. John Heywood. It consists of two sections; the first part deals with the radio-active elements, and the second is an introduction to the study of organic chemistry.

WE have received from the Art. Institut Orell Füssli, of Zurich, Nos. 177, 178, and 179 of their "Illustrated Europe" series of handbooks. The three parts are bound together in a convenient little volume with the title "Grisons Oberland." The guide book is by Dr. Chr. Tarnuzzer, and a historical sketch has been contributed by Prof. J. C. Muoth. The translation into English was done by Dr. and Mrs. Spöndly-Blakiston. Visitors to this interesting part of Switzerland will find interesting scientific, historical, and topographical information in this guide book. The book may be obtained in this country from Messrs. Hachette and Co.

MESSRS. OLIVER AND BOYD have published the ninth volume of the "Reports from the Laboratory of the Royal College of Physicians, Edinburgh." The volume is edited by Sir J. B. Tuke and Dr. Noël Paton. The papers included fall under two categories; the first comprises fourteen papers describing researches on the ductless glands under the Mason fund, and the second consists of general researches in physiology, pathology, and pharmacology.

WE have received from Mr. John Grant, of Edinburgh, a catalogue of scientific books, chiefly on botany, zoology, and geology, and a catalogue of recent purchases—including some well known works of science—all of which are offered at greatly reduced prices.

MR. W. BUTLER, Southport, has devised a new type of camera stand—called the Swingcam—to facilitate the photography of natural history subjects. The stand enables a photographer to point the lens of a camera at any angle and fix it in that position, without the use of a swinging back or front or any other independent attachment. The Swingcam tripod head can be fixed in a horizontal or vertical position, or at any angle, and is also capable of being inverted if desired. Naturalists and others who occasionally have to use cameras in awkward positions will no doubt find these devices a convenience.

NEW editions of two standard works already reviewed in these columns have just been received from Mr. Gustav Fischer, Jena. One is the seventh edition of the "Lehrbuch der Botanik" by Profs. Strasburger, Noll, Schenck and Karsten, and the other is the seventh edition of Dr. R. Hertwig's "Lehrbuch der Zoologie." Both works have been revised, so that they will maintain their high position among text-books of science.

WE have received from Messrs. Henry Sotheran and Co., 140 Strand, W.C., a copy of their latest catalogue of second-hand books, including numerous scientific works; and from Messrs. John Wheldon and Co., 30 Great Queen Street, W.C., a catalogue of a miscellaneous collection of books, comprising many dealing with biology, geology, and mathematics.

MESSRS. DAWBARN AND WARD, LTD., have published a second revised edition of "Photographic Failures: Prevention and Cure," by "Scrutator" of the *Photogram*.

OUR ASTRONOMICAL COLUMN.

NEWLY DISCOVERED NEBULÆ.—In No. 4013 of the *Astronomische Nachrichten* Prof. Max Wolf announces the discovery of a small, but beautiful, nebula the position of which, referred to the equator of 1900·0, is as follows:— $\alpha = 13h.\ 58m.\ 33{\cdot}44s.$, $\delta = -9^\circ\ 39'\ 36''$. This object was discovered on a plate exposed during a search for minor planet (126), Velleda, and is of a spiral form, of the unusual S-shaped variety, the nucleus being of the fourteenth magnitude. Its diameter in R.A. is about $0'{\cdot}75$, and in dec. about $1'{\cdot}0$.

A second nebula of especial interest was found in the position (1900·0) R.A. $= 13h.\ 58m.\ 15{\cdot}17s.$, $\delta = -9^\circ\ 40'\ 10''$. This object is $1'$ in length along its major axis, which has a position angle of about 120°, and is of the Andromeda nebula form.

THE BRUCE TELESCOPE REFERENCE PHOTOGRAPHS.—When the 24-inch Bruce telescope of the Harvard College Observatory was being planned it was expected that the instrument might be useful in assisting in the discoveries of new satellites, and this expectation was realised in the discovery of Phœbe. A number of plates of each planet have been taken since 1893, and of these Prof. Pickering now gives the details as to object photographed, exposure, date and region, in Circular No. 97 of the Harvard College Observatory, hoping that the knowledge of their existence may assist other observers of possible satellites. The list includes 12 plates exposed for Mercury, 2 for Mars, 6 for Vesta, 21 for Jupiter, 12 for Uranus, and 3 for Neptune. The Saturn plates were fully described when the manner of the discovery of Phœbe was related in a former publication. The limiting magnitude of the objects shown on these plates may be taken as 17·0 or 17·5, and therefore the photographs may prove useful in the correction of the elements of Jupiter's newly discovered satellites when more is known of the positions of these two objects.

COMET 1904 II. (1904 *d*).—A continuation of the ephemeris for comet 1904 *d* is given in No. 4012 of the *Astronomische Nachrichten* by Herr M. Ebell.

This comet is now only about one-sixth as bright as when discovered, and is gradually becoming fainter. Its position on May 26, according to the ephemeris, will be α (true) $= 2h.\ 23m.\ 48s.$, δ (true) $= +64^\circ\ 50'$, which is about 2° south of ι Cassiopeiæ, and the object is travelling slowly towards the constellation Camelus with a very slightly increasing declination.

TWELVE STARS WITH VARIABLE RADIAL VELOCITIES.—Further results of the spectrographic work performed by the D. O. Mills expedition from Lick Observatory to the southern hemisphere are published in Bulletin No. 75 of that observatory.

Twelve stars have been found by Prof. Wright and Dr. Palmer to be spectroscopic binaries, some of them, mentioned below, having features of especial interest. α Phœnicis has a period of about 190 days. The system of θ Eridani has been found to be very similar to that of Mizar, the brightest component, θ_1, having a composite spectrum similar to that of the star named. α Puppis, α Volantis, α Carinæ, and κ and p Velorum are amongst the other stars of which the radial velocities have been found to be variable.

DOUBLE "CANALS" ON MARS IN 1903.—In Bulletin No. 15 of the Lowell Observatory Mr. Lowell gives, and discusses in detail, the results of his observations of the Martian "canals" during 1903. Before proceeding to the account of the actual observations, he comments on the various theories which have been advanced in argument against the reality of the "doubling" phenomenon. The "diplopic" or out-of-focus theory is refuted for five reasons, the chief of which is that for any special epoch the width of each individual double canal remains constant.

The "interference" theory is met by the statements that in the case of these features there is no bright streak such as would be necessary to produce the two dark streaks to give the idea of a double canal, and that the width of each double canal does not vary with the aperture employed. Lastly, the "illusion," or, as Mr. Lowell refers to it, the "Small Boy," theory is considered,

the chief argument against it being that the ambiguity of real and false effects only exists at the limit of vision, whereas most of the canals considered are, *when well seen*, far within this limit.

A number of interesting points concerning the canal systems are deduced from the 1903 observations, but only one or two of the more striking may be mentioned here. (1) The majority of the double canals do not exceed 3°·2 (degrees on the planet's surface) in width; (2) at the time of maximum visibility the two members of each double are generally of equal strength, but as they wane one of them usually becomes apparently stronger than the other; (3) the double canals appear to congregate in special longitudes and latitudes, in the latter case especially favouring the equatorial regions, a fact which Mr. Lowell urges as an argument against the "diplopic" theory; (4) the double canals are peculiar to the lighter regions of the planet's surface, although single canals are, apparently, just as numerous in the darker as in the lighter regions; the double canals, however, are always connected, directly, or through the medium of similar objects, with the darker areas.

CATALOGUE OF NEW DOUBLE STARS.—Prof. Hussey's ninth catalogue of double stars, discovered with the 12-inch and 36-inch refractors of the Lick Observatory, and mostly measured with the latter instrument, is contained in Bulletin No. 74 of that observatory. The preceding catalogues have severally appeared in Nos. 480, 485, and 494 of the *Astronomical Journal*, and Nos. 12, 21, 27, 57, and 65 of the Lick Observatory Bulletins.

The present publication gives the catalogue and D.M. numbers, the position and the distance and position-angle determined at each observation for each of the double stars recorded. The catalogue numbers extend from 801 to 1000 inclusive, and run consecutively.

THE ROYAL SOCIETY CONVERSAZIONE.

MANY instruments and devices of scientific interest were shown at the Royal Society's conversazione on Wednesday, May 17. As usual, the exhibits illustrated methods and results of recent work in various branches of science, and the subjoined summary of the official catalogue contains a few particulars relating to them.

In the course of the evening lantern demonstrations were given in the meeting-room by Dr. E. A. Wilson, Sir Oliver Lodge, and Mr. Perceval Landon. Sir Oliver Lodge demonstrated the use of electric valves for the production of high-tension continuous current. Electric vacuum valves, which it is now found were suggested in a letter by Sir George Stokes twenty years ago, have as their function the *entrapping* of a portion of electricity by permitting its passage in one direction and stopping its return. They therefore can be employed to accumulate electricity supplied from an intermittent or jerky source and to store it at a steady high potential; so that it may thereafter maintain a current through a very high resistance, as in electrostatics, and may produce X-rays, or point-discharge, or other continuous high-tension effects, and enable a small portable coil to imitate some of the effects of a much larger one by storage and accumulation of impulses. Among the applications contemplated are the separation of metallic fume and the dissipation of fog.—Dr. Edward A. Wilson showed a number of Antarctic views illustrating the life and work done on board the *Discovery* during the years 1902 to 1904, and views of the seals, penguins, and other birds met with in the Antarctic circle; and Mr. Perceval Landon exhibited pictures of the road to Lhasa.

The other exhibits are here grouped together according to subjects more or less closely related to one another.

Specimens illustrating the action of light and of radium upon glass: Sir William Crookes, F.R.S. (1) It is well known that many samples of colourless glass containing manganese slowly assume a violet tint when exposed to sunlight. In some specimens of glass exhibited the pieces were of all depths of tint, from deep violet, almost black in thick pieces, to pale amethyst. Analysis shows the glass to contain manganese. Heating the glass in a covered crucible to its softening point discharges the colour, leaving the glass white and transparent. The coloration is not superficial. On immersing a piece of the coloured glass in a liquid of about the same refractive index as itself, the colour is seen to have penetrated throughout the mass. Radium, acting for a few days, even through quartz, will produce as intense a coloration in a piece of this glass as exposure to the sun on the Pampa has taken years to effect. Six pieces of glass from the greenhouses at Kew Gardens illustrated changes which took probably about fifty years to complete in our climate. Purple spots were produced on two of these specimens by Sir William Crookes by the action of 15 milligrams of radium bromide in a quartz tube in the course of ten days, the beginning of change being well marked at the end of two days. In a specimen of manganese glass exposed to light for forty years as a pane of a greenhouse, the ends of the glass which had been protected from light by the window frame were colourless. In the expectation that radium might have a reducing effect on the manganese compound, Mr. F. Soddy submitted a portion of the pane to the action of 30 milligrams of radium bromide for three days in May, 1904. The colour, however, instead of being diminished, was intensified. Specimens were also shown illustrating the coloration of glass, quartz, and fluorspar by the β rays of radium.

Action of actinium or emanium emanation on a sensitive screen: Sir William Ramsay, K.C.B., F.R.S. Actinium or emanium are different names, adopted by Debierne and Giesel respectively, for the same substance, separable from pitchblende, and accompanying lanthanum. It gives off an emanation, of which the period of activity is very short—a few seconds. When this emanation impinges on a sensitive zinc sulphide screen, the screen becomes luminous. The luminous patch can be blown away, and in a second or two reappears.—Phosphorescence caused by the β rays of radium: Mr. G. T. Beilby. Phosphorescence of calcspar and other substances—(1) during exposure to the rays; (2) after removal from the rays; and (3) revived by heat after secondary phosphorescence has died down. The storage of phosphorescence and the coloration effects are due to partial electrolysis of the calcium carbonate or other substance by the stream of negative electrons. A proportion of the ions re-combine at once, others continue to re-combine after the rays have ceased to act, and the remainder only re-combine when the mobility of the crystal molecules is increased by heat.—Skiagrams of the hands of Machnow, the Russian giant, and of O'Brien, the Irish giant: Mr. S. G. Shattock.

Large echelon spectroscope: Prof. A. Schuster, F.R.S. This echelon spectroscope, constructed by Messrs. Adam Hilger, Ltd., consists of 33 plates, and has a resolving power equal to that of an ordinary grating of 329,000 lines in the first order.—A hand refractometer: Mr. G. F. Herbert Smith. By means of this form of refractometer the refractive indices of any translucent substance, the refractive power of which lies within the effective range of the instrument, 1·400 to 1·760 approximately, may be determined with ease and celerity, to units in the second place of decimals if ordinary light, and to two or three units in the third place of decimals if the monochromatic light emitted by a volatilising sodium salt be the source of illumination.—The Ashe-Finlayson comparascope: Mr. D. Finlayson. This accessory to the microscope has been designed to enable the images of two different objects, separately mounted, to be projected side by side into the field of view, thereby enabling a thorough comparison to be made of their respective points of difference and resemblance. The apparatus consists of a prism placed above the primary objective which reflects to the ocular the rays from a secondary objective placed at right angles to the optic axis of the microscope.—(1) Torsion balance, used in radiation pressure measurements, by Nichols and Hull; (2) vacuum tube, of Nichols and Hull, to illustrate the repulsion of comet tails by the sun: Prof. E. F. Nichols.—An optical appliance to facilitate visual perception of ultra-microscopic particles: Mr. Carl Zeiss. The apparatus consists of a projection table provided with an arc lamp, optical bench, two projection aplanats, and a precision slit. (The use of sunlight instead of the arc lamp is preferable.) Particles of far less than half a wave-length can be made visible with this apparatus.—

Mechanical lantern slide illustrative of the phenomenon of a total solar eclipse: Mr. W. Shackleton. A white disc representing the sun is projected on a screen; by moving an opaque disc representing the moon, this is gradually obscured, and the preliminary partial phases of a total solar eclipse are shown. A moment before complete obscuration a twin shutter is opened, which allows the corona and chromosphere to be projected, thus reproducing totality, which may last as long as desired.—Stereoscopic views of the sun and stars of estimated parallax: Mr. T. E. Heath. The perspective drawings were made from a plan and elevations in which the scale of stellar distances was ten light-years to 1 inch, and of stellar discs such that the sun (or a star which gives equal light) was 1/50th of an inch in diameter. The magnitudes were made to vary with the varying distance of the spectator.—(1) Microscope and goniometer stage for examining the optical qualities of minute grains of sand; (2) set of petrological quartz wedges; (3) photomicrographic camera, designed by Mr. J. W. Gordon for taking small direct photomicrographs while the instrument is in use after observation without attention to the adjustments: Messrs. R. and J. Beck, Ltd.

(1) Photomicrographs of section of gun tube showing change in structure of steel after 2000 rounds; (2) photomicrographs of alloys of aluminium with nickel; (3) photomicrographs of alloy of copper with cobalt and nickel: Dr. Hodgkinson, Captain Playfair, R.A., and Mr. Coote.—(1) Apparatus for polishing and preparing metals for microscopic examination; (2) specimens of steels in the cast and forged condition containing phosphorus: Mr. J. E. Stead, F.R.S.—Transverse sections of slip-bands and other microscopic features of metallic surfaces: Mr. W. Rosenhain.—A series of alloys of iron and steel tested at liquid air temperature: Mr. R. A. Hadfield. The specimens showed the effect of liquid air (temperature $-182°$ C.) upon almost pure iron (Swedish charcoal iron "S.C.I.," 0·04 carbon, 99·82 iron) and a large number of alloys of iron with other elements. The well known ductility of iron disappears, while its tenacity is more than doubled. Similar effects occur with nearly all the alloys of iron with carbon and other elements, except those containing nickel, which metal appears to modify considerably the embrittling effect of low temperatures upon iron.

Clock and chronometer by Thomas Mudge: Mr. A. Mallock, F.R.S. The clock was made about 1776, and contains Mudge's moon motion. Mudge's object in making this motion was to show that any desired velocity ratio could be approximated to very closely with comparatively few wheels. The train of wheel-work he employed makes the mean lunation 0·03 second less than the actual mean lunation, that is, the error is less than 1 in 2½ millions. There are other remarkable features in this clock connected with the balance wheel, escapement, and temperature correction.—(1) Tangent-micrometer for theodolites, &c.; (2) endless-tangent screw for sextants: Mr. E. A. Reeves. By the addition of a micrometer "drum," and a simple arrangement for clamping the outer rim or dial carrying the numbers, combined with a special indicator, a carefully constructed tangent-screw serves also as a micrometer, and renders it possible to read the arc with the same accuracy as with the usual form of micrometer, while the instrument need not be larger than the ordinary vernier theodolite. The sextant device consists of a tangent-screw constructed with an endless thread, by means of which the vernier arm can be made to pass from any one part of the arc to another. For making rough contacts the tangent-screw is raised from the arc by means of a lever pressed by the finger. When the pressure on the lever is released the tangent-screw, actuated by a spring, again comes in contact with the arc, and serves as a clamp.

A direct reading cymometer for measuring the length of the waves used in wireless telegraphy: Prof. J. A. Fleming, F.R.S. The instrument consists of a sliding tubular condenser and an inductance coil, the capacity and inductance being varied together in the same proportion by one movement of a handle. The circuit is closed by a copper bar, which is placed alongside the aërial wire indicating the electric waves. The handle of the cymometer is then moved until a neon vacuum tube used as an indicator shines most brightly, and thus determines when the cymometer circuit is tuned to the frequency of the aërial. A pointer moving over a scale then indicates the wave-length of the radiated wave in feet or metres.—An oscillation valve for rectifying electrical oscillations and rendering them measurable on an ordinary galvanometer: Prof. J. A. Fleming, F.R.S. The valve consists of a bulb enclosing a carbon filament made like an incandescence lamp. The filament is surrounded by a metal cylinder. The bulb is highly exhausted. When the filament is incandescent, negative electricity can move through the vacuum from the hot filament to the cylinder, but not in the reverse direction. Hence the arrangement can separate out the two opposite currents in an electric oscillation. It can be used in combination with a dead beat galvanometer as a receiver in wireless telegraphy. The valve replaces the coherer and other appliances, and the signals are given by long and short deflections of the galvanometer.—(1) Resonance induction coil and high potential apparatus; (2) resonance electromagnet: Messrs. Isenthal and Co. Electrolytic condensers of very large capacity are charged from the mains through the primary of a suitably wound induction coil, and the circuit broken and reversed at zero potential by means of a motor-driven commutator of special construction. The advantages are:—no motor transformer is required in primary circuit, no rectifying device in secondary circuit, and there are no interruptors to be cleaned. The apparatus enables a current to be converted sparklessly into pure sine current suitable for space telegraphy. An electromagnet excited from a source of this kind exhibits peculiar physical and physiological phenomena.—(1) High-tension resonance transformer; (2) X-ray stereoscope: Mr. Russell Wright. The special form of "step-up" transformer exhibited works direct from the alternating current mains, and produces an alternating discharge of sufficient tension for X-ray work or high-frequency effluve. By means of a small revolving shutter, driven by a synchronous motor, between the observer's eye and two X-ray tubes, stereoscopic images could be clearly seen on an X-ray screen.

High temperature electric furnaces: Director of the National Physical Laboratory. These furnaces are constructed of rare earths such as are used in Nernst lamps. They are available for temperatures between 800° C. and 2000° C. The apparatus used in a recent determination of the melting point of platinum was shown at work, in addition to that for other experiments of a similar character.—New models of laboratory electric furnaces: Mr. R. S. Hutton. The furnaces consist of a carbon tube, rod, or plate heated by an electric current. In the tube furnaces the carbon is surrounded by some material of low thermal conductivity, which also serves to protect the hot tube from oxidation. The substance to be heated is placed in a carbon boat or crucible inside the tube, and can thus be brought to a very high temperature. The method employed for conveying the current to the carbon by soldering water-jacketed sleeves to the electro-coppered ends of the carbon forms a novel feature of the construction.

Photographs taken in China by the Carnegie expedition under Mr. Baily Willis in 1904, illustrating a presumably Glacial deposit underlying the base of the Cambrian rocks of the region: Sir Archibald Geikie, Sec.R.S.—Photographs, cast, and model of skull of Diplodocus, a Jurassic dinosaur from Wyoming, and other fossils from the middle west of North America: Dr. W. J. Holland.—Remains of fossil mammals from Crete: Miss D. M. A. Bate. Numerous mammalian remains were found in 1904 in the Pleistocene cave and fresh-water deposits of Crete. These include remains of the following animals:—antelope, deer, elephant, pigmy hippopotamus, shrew, and two species of rodents.—The great Indian earthquake, April 4: Prof. J. Milne, F.R.S. Five seismograms of this disturbance were shown from Shide, Isle of Wight. (1–2). Open diagrams on smoked paper showing north-south and east-west motion. (3) Open diagrams of east-west motion on photographic paper. The instrument was a Milne horizontal pendulum. (4–5) Photographic records from a pair of Milne horizontal pendulums vibrated north-south and east-west. The exhibit also included seismograms of east-west

motion from Edinburgh, Paisley, Beirut, and Toronto.—Charts of the Gulf of St. Lawrence, showing the co-tidal lines at mean time of Quebec: Captain Tizard, C.B., F.R.S.—Photographs of the "Cullinan" diamond: Sir William Crookes, F.R.S.

Microscopic preparations illustrating the development of calcareous spicules in various invertebrate animals: Prof. E. A. Minchin and Mr. W. Woodland. Calcareous spicules are small skeletal elements to be found in most of the lower animals. These spicules assume varied and often beautiful forms, those of sponges and "sea cucumbers" (Cucumariidæ and Synaptidæ) being especially striking in this latter respect, and are built up in all instances by the agency of scleroblasts—small nucleated protoplasmic masses which deposit the lime. The causes underlying the production of the curious forms which these spicules assume (triradiates, perforated plates, wheels and anchors, &c.) are not by any means yet understood, but are probably several in number, some being purely mechanical in nature, others, perhaps, being those which give rise to crystals.—Cellular constituents peculiar to cancerous and reproductive tissues: Prof. J. B. Farmer, F.R.S., Mr. J. E. S. Moore, and Mr. C. E. Walker. In the cells of malignant tumours, structures known as "Plimmer's bodies" are present in most cases. These structures have been regarded as parasitic organisms or as specific cellular peculiarities confined to such malignant tissues. They have recently been identified as also being present in normal reproductive tissues. They form a definite organ of the cell during its conversion to a spermatozoon, and they also can be identified in the two preceding divisions. They are absent from other cells of the body.—The simplest kind of protoplasm: Dr. Charlton Bastian, F.R.S. One drop of a fluid swarming with common bacteria had been introduced into one ounce of distilled water containing ten grains of neutral ammonic tartrate in solution. The bacteria grow freely in this fluid, and as the constitution of the ammonia salt is $2NH_4O, C_8H_4O_{10}+2HO$, they must fashion their protoplasm in some way from C, H, O, and N only, though sulphur and phosphorus, one or both, are commonly regarded as necessary constituents of living matter.

The parasite of "kala azar": Brevet Lieut.-Colonel W. B. Leishman. This protozoal organism is found in the spleen and other organs in cases of "kala azar," an extremely fatal disease occurring in epidemic form in Assam, and also, in endemic form, in other parts of India and the tropics. Nothing is yet known as to the mode of infection or as to the life of the parasite outside its human host. In artificial cultures it develops into a flagellated organism closely resembling a trypanosome. Specimens and sketches were shown of the parasites as they occur in the tissues, and of the flagellated forms into which they develop in artificial cultures.—The isolation of *B. typhosus* from water by means of alum precipitation: Mr. H. S. Willson. Alum is added to the infected water in the proportion of 0·5 gram to the litre. When the precipitate of aluminium hydrate has fully formed, the water is centrifugalised and the sediment containing most of the bacteria present in the water is spread on plates of suitable media, and incubated at 42° C. The precipitate, which is known to be destructive to many water and sewage organisms, has no germicidal action on *B. typhosus*.

(1) Stone adze heads in various stages of manufacture, and chips from the neighbourhood of Suloga, Woodlark Island, British New Guinea; (2) photographs of straight-haired individuals from Nara district central division, British New Guinea; (3) wood carvings and drawings, principally from Massim district, British New Guinea: Mr. C. G. Seligmann. Specimens of cross-bred maize illustrating inheritance in accordance with Mendel's law: Mr. R. H. Lock.—Living representatives of the Plymouth marine fauna: Marine Biological Association. Material obtained with the dredge from certain typical grounds in the neighbourhood of Plymouth was shown, together with representatives of the animals living on each ground.—Photographs illustrating young cuckoo in the act of ejecting egg and young bird from nest of foster-parent: Mr. W. Percival Westell.

A new problem on superposition: Mr. H. E. Dudeney. This was a demonstration that an equilateral triangle can be cut into four pieces that may be re-assembled to form a square, with some examples of a general method for transforming all rectilinear triangles into squares by dissection.

Oil painting, a Friday evening lecture at the Royal Institution: Mr. H. J. Brooks.

ATMOSPHERIC ELECTRICITY OBSERVED FROM BALLOONS.

IT is now some years since attempts were first made to investigate the electrical conditions of the upper atmosphere by aid of manned balloons; but it is only within the last three years that the difficulties of the observations and the proper methods to be used have been anything like understood.

Measurements of the normal potential gradient were first attempted. The early observers worked very much in the dark, Linke being the first, in 1901, to investigate the errors due to the mere presence of the balloon itself. He found that for the influence of an uncharged balloon to be small enough to be neglected, the upper of the two collectors used must be at least 10 metres below the basket.

Linke also investigated the efficiency of different forms of collectors. The original form of collector used in balloon work was a modification of Kelvin's drop collector. A wire was lowered from an insulated vessel out of which water flowed and ran down the wire; the drops forming on the end of the wire and then falling off brought the whole wire to the potential of the air at its end. There are many objections to this form of collector; it is very slow in action, uses a large quantity of water, and will not work when the temperature falls below freezing. Flame collectors are obviously out of the question for balloon work on account of their danger, and, much to the regret of the experimenters, radium did not come up to expectation. The difficulty with radium collectors is that the radium ionises a large volume of air, which, on account of the absence of relative motion between the balloon and the surrounding air, travels along with the balloon and completely alters the electrical conditions of the atmosphere in its neighbourhood. By a simple device Linke has finally overcome all difficulties connected with the collectors. A vessel containing spirits is insulated on a shelf fastened to the outside of the basket. From this vessel hangs a long thin lead or other flexible pipe. At the lower end of the pipe is a nozzle which forms the collector proper. As stated above, the collector must be 10 metres below the balloon; thus there is at least a 10-metre head of liquid acting at the nozzle. The pressure due to this causes a very fine jet to escape from a pinhole in the nozzle. As the jet breaks up into exceedingly fine drops, a very rapid collector action takes place. Collectors of this form have acted splendidly, and their use makes it possible to measure the potential gradient with accuracy and ease.

The rate of dissipation of electricity from a charged body, and the degree of ionisation of the air, have also been made subjects for investigation in the upper atmosphere. Ebert and Linke have devoted several ascents to measurements of the dissipation, and Ebert designed the first instrument to measure the natural ionisation of the air; but the ionisation has been most carefully investigated by Gerdien, who improved Ebert's instrument so that it measures not only the ionisation, but the conductivity of the air also.

It was when making these latter investigations that a number of difficulties connected with the casting of ballast were first observed. Ebert found that the pouring of sand from the ballast bags so highly charged the balloon with friction electricity that electrical observations became impossible. Gerdien found that after sand had been cast the balloon remained for some minutes in an atmosphere filled with fine sand dust, which greatly affected the measurements of the ionisation. Linke also found that on account of the sudden upward acceleration given to the balloon after sand had been cast the position of the electroscope leaves changed without any change of voltage. Gerdien was the first to overcome these difficulties. Besides sand, he took two large watertight sacks filled

with water. By having pipes and taps fitted to the sacks water could be discharged as desired. Sand still remained the ordinary ballast; but when electrical measurements were being made water only was used. In order to prevent the water freezing in the cold upper atmosphere, Gerdien filled the sacks with boiling water, which, experience proved, kept sufficiently warm to prevent freezing before it was all used. This method was found to be entirely satisfactory, for it not only got over all difficulties connected with the sand, but by regulating the flow of the water much greater control could be exercised over the balloon than had before been possible with sand.

These and other difficulties have been so recently recognised and overcome that trustworthy results have as yet hardly been obtained, but the observations appear to justify the following conclusions:—

The normal potential gradient remains positive to the highest point yet investigated (5900 metres by Gerdien), but decreases in magnitude as the height increases. This points to the lower regions of the atmosphere containing a positive charge equal to the negative charge on the earth's surface, so that the globe as a whole is not charged.

The number of ions in a cubic metre of air is the same at all heights.

Electricity is dissipated more rapidly from a charged body the higher it is in the atmosphere, this being, no doubt, due to the greater ease with which ions move in rarified air.

These results require further verification before they can be accepted as final, and it is to be hoped that facilities will be forthcoming for the investigations to be followed up in this country. It is a strange fact that no Englishman has yet devoted himself to a study which combines science and sport in such an attractive manner.

GEORGE C. SIMPSON.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The syndicate the proposals of which with regard to the previous examinations were thrown out by the Senate last term, was elected to consider the studies and examinations of the University, and, although it has so far considered but one examination, a determined attempt is being made to bring its deliberations to a close. The period for which the syndicate was appointed lapses at the end of this term, and the grace which authorises its re-appointment will to-day be "non-placetted" in the Senate. A short time ago four members were added to the syndicate. Their nomination was not objected to, though the action of the council in appointing them was termed inexpedient. It seems a strange piece of courtesy to acquiesce in the appointment of men like the master of Gonville and Caius, Mr. S. H. Butcher, late professor of Greek in Edinburgh, Dr. Adam, and Mr. Hardy to a syndicate which the opponents of change intended, so far as lay within their power, to render moribund.

The natural sciences tripos continues to increase. There are 149 candidates entered for part i. and 30 candidates for part ii., both of which began this week. In the first part of the mathematical tripos there are 57, and in the first part of the classical tripos there are 102 candidates, in the second part 12. The entrances for the mechanical sciences tripos, part i., are 45.

The Board of Agricultural Studies reports a continuous increase both in the number of students attending the agricultural courses and in the number presenting themselves for the examinations. The number of students is now close upon fifty, and shows an increase of seven within the last twelvemonth.

The honorary degree of M.A. will to-day be conferred on Mr. Robert Stephenson, late chairman of the Cambridgeshire County Council, in recognition of his services to education, and especially to the promotion of agricultural education in the university.

The Rede lecture will be delivered on Saturday, June 10, at 11.30 a.m., by Sir Francis Younghusband, K.C.I.E. His subject is "Our True Relationship with India."

The council of the Senate has promulgated a grace proposing that a syndicate be appointed to consider the desirability of establishing in the university a diploma in forestry, and to draw up, if it thinks fit, a scheme of instruction and examination in forestry; that it be empowered to consult with any persons or bodies; and that it report to the Senate before the end of the Lent term, 1906.

The next combined examination for sixty-two entrance scholarships and various exhibitions at Pembroke, Gonville and Caius, King's, Jesus, Christ's, St. John's and Emmanuel Colleges will be held on Tuesday, December 5, 1905, and following days, commencing at 9 a.m. on Tuesday, December 5. Mathematics, classics, and natural sciences will be the subjects of examination at all the above-mentioned colleges, and certain colleges examine in history, modern languages, and Hebrew.

OXFORD.—Dr. Henry Wilde, F.R.S., has presented 100*l.* to the Hope Department of Zoology for the purchase and preparation of specimens illustrating mimicry and protective resemblance.

The Romanes lecture for 1905 will be delivered by Prof. Ray Lankester, F.R.S., in the Sheldonian Theatre on Wednesday, June 14, at 2.30. The subject of the lecture will be "Man and Nature."

Mr. R. de J. Fleming Struthers has been elected to a senior scholarship in chemistry at Exeter College.

The Junior Scientific Club will hold a conversazione at the Museum on Tuesday, May 30.

MR. E. P. CULVERWELL has been elected to the professorship of education founded by the Board of Trinity College, Dublin, for a period of five years.

A REUTER telegram from Toronto reports that the Ontario Government has announced a provisional grant of 100,000*l.* to the University of Toronto toward the proposed new buildings which, it is estimated, will cost 320,000*l.*

IT has been announced, *Science* states, that the trustees of Columbia University have received 100,000*l.* from an anonymous donor for the construction of a new college hall; and that the Legislature of Minnesota has made direct appropriations for the University of Minnesota for the next two years amounting to 142,000*l.*, besides 12,000*l.* derived from the insurance on the old main building, destroyed by fire last September.

AN International Exhibition of Pedagogy, under the patronage of H.M. the King of Spain and of H.M. Queen Maria Christina, will be held in Barcelona from May to October. Particulars as to the scope of the exhibition and the conditions attaching to exhibits are given in the official programme, a limited number of copies of which can be obtained on application to the Director of Special Inquiries and Reports, Board of Education Library, St. Stephen's House, Cannon Row, Whitehall, London, S.W.

PRESIDING at the annual meeting of the British and Foreign School Society, Mr. A. H. D. Acland moved the adoption of the report on the year's work of the association. During the course of his speech, he remarked that in many schools too much is done for the brain and too little for the body. If hygiene, instead of being merely a special subject, were made part of the teacher's general outfit, much would be done for the health of the nation. Mr. Acland said he hopes also that by degrees the pest of examinations will be modified and got rid of—a matter in which the old universities are among the greatest sinners. Whoever could wipe out two-thirds of the examinations would be one of the greatest benefactors of the human species.

THE question of the concentration of the teaching of the preliminary and intermediate subjects of the medical curriculum in London at a few centres has long occupied the attention of those interested in medical education, as it has been felt that this step must result in greater efficiency in teaching, as well as economy in expenditure. The Westminster Hospital Medical School has been the first to take definite action in the matter, and has just completed negotiations with King's College by which arrangements have been made for the teaching of physics, chemistry, biology, anatomy, physiology, and materia medica (that is to say, the subjects of the preliminary and intermediate examinations) to Westminster students

of King's College. Students will enter Westminster Hospital Medical School as in the past, and will remain Westminster men; they will not become matriculated students of King's College, but they will be taught the earlier subjects of study at that institution. The scheme will come into effect at the commencement of next winter session in October. At the same time, the teaching of the subjects of the final examination is being completely re-organised. It is believed that this commencement of a probably more general concentration of the teaching of the preliminary and intermediate subjects of the curriculum cannot but promote the best interests of medical education in London.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 9.—"On some Continuous Observations of the Rate of Dissipation of Electric Charges in the Open Air." By Dr. C. Coleridge **Farr**. Communicated by Dr. C. Chree, F.R.S.

During part of 1902 and 1903 the author resolved to take as many observations of the rates of dissipation of electric charges as possible, and to continue them over the whole day, and, when opportunity offered, over longer periods.

The observations were made on the Canterbury Plains of New Zealand, about 20 feet above sea-level, and five miles due west from the sea coast. The apparatus used was Elster and Geitel's[1] *Zerstreuungsapparat*. Corresponding observations were made of the direction and intensity of the wind (Beaufort), the humidity, and the potential difference between a point about 10 feet above the ground and the earth. This was determined by a Kelvin portable electrometer and a water-dropper.

The dissipation apparatus was read by a telescope, and at night it was illuminated by a bull's-eye lantern, but only during the actual time of reading.

The conductivity of the air is very irregular, but on an average negative electricity is dispersed more rapidly than positive.

$$\text{Taking } q = \frac{\text{conductivity of air for } -\text{ve electricity}}{\text{conductivity of air for } +\text{ve electricity}},$$

six ordinary days, embracing several hundreds of observations, gave an average of $q = 1.16$.

Yet on several occasions for some hours together during these six days, positive electricity was dissipated the more rapidly. The examples considered apparently indicate that a low value for q is, as might be expected, accompanied with a reversal of sign of the atmospheric charge. On one occasion, however, the potential became -185 volts with q about unity.

Again, considering the six days only, as more typical of ordinary conditions than two others to be referred to, there is distinct evidence of a double maximum and minimum value for the conductivity throughout the day for charges of both signs.

Of two other days, viz. February 1 and 2 and December 15 and 16, the former exhibits no distinct maxima and minima, but a strong south-west gale was blowing; the latter day is incomplete.

Observations on February 1 and 2, and on March 1 and 2, during south-west gales gave a much higher value for the conductivity for both positive and negative charges than usual. Since the wind on these two days was in the same direction, there is only a slight amount of evidence that the excessive conductivity is due to the strength rather than to the direction of the wind.

Two days not yet mentioned, viz. February 18 and March 16, may now be referred to. On the first of these a strong gale from the north-west was blowing when the observations were begun. On the latter, at 6.30 a.m., it was calm; at 8 a.m. there was a light south-west wind, and at 9.30 it was blowing strongly from the north-west with a characteristic falling barometer. These "nor'westers" blow over a range of mountains reaching 7000 feet, and deposit their moisture on the western slopes, though the rain often extends to the eastern side. In Christchurch they are invariably dry and hot, being of the nature of "Foehn" winds, and have a depressing effect upon most people.

[1] Elster and Geitel, "Terrestrial Magnetism," vol. iv., p. 213 *et seq.*

Though the above days are the only two of the class upon which, so far, the author has taken dissipation observations, yet potential observations indicate that the winds are negatively charged relatively to the earth, which is contrary to the usual condition. On both days the dissipation curves show marked peculiarities. The earliest observation, at 11.15 a.m. on February 18, gave $q = 0.4$, with a negative potential difference between water-dropper and earth of -300 volts at 10.20 a.m., -150 volts at 11.40 a.m., and -50 volts at 12.45 p.m. Corresponding with this rise of potential there is also a marked rise in the value of q.

On March 16 the whole history is apparent: At 7.30 a.m. the wind was light south-west, $q = 1.3$, potential $+90$ volts. At 9.45 a.m., wind north-west, strong, $q = 0.7$, potential -250 volts. At 10.30 a.m., wind north-west, strong, $q = 1.1$, potential -100 volts approximately. The north-west wind seemed then to have thoroughly established itself. The values of q became less and less, the curves indicating the conductivity of the air for positive and negative charges diverging rapidly, that for positive reaching a high value, whilst the negative curve reached remarkably low values. Corresponding with the extremely low value for q the potential reached its greatest negative value, -1885 volts. After this q increased and the negative potential decreased, until at 4.30 p.m. $q = 0.94$, potential -30 volts.

March 30.—"On a New Type of Electric Furnace with a Re-determination of the Melting Point of Platinum." By Dr. J. A. **Harker**. Communicated by Dr. R. T. Glazebrook, F.R.S.

The first part of the paper deals with a description of a new type of electric furnace for the attainment in absence of noxious gases of temperatures between 800° C. and 2200° C. The conductor conveying the electric current is a tube of solid electrolytes similar in composition to the filament of a Nernst lamp. An essential feature is that, for many purposes, the usefulness and life of a furnace constructed in this way may be much increased by adopting a "cascade" system of heating. That is, the energy supplied may be divided, so that only sufficient is put through the tubular conductor itself to raise its temperature, say 1000° C. above its surrounding, the surrounding itself being maintained at 1000° C., thus enabling a temperature of 2000° C. to be attained in the tube without straining it unduly.

The regulation of temperature in small furnaces of this type is so perfectly under control that very well defined melting points may be taken with very small quantities of substance.

The second half of the paper deals with a re-determination of the melting point of platinum by the thermo-electric method in these furnaces, the highest value found being 1713° C., the lowest 1702° C., and the mean result of the experiments 1710° C. ± 5° C.

May 11.—"The Effect of Plant Growth and of Manures upon the Soil: the Retention of Bases by the Soil." By A. D. **Hall** and N. H. J. **Miller**. Communicated by Prof. H. E. Armstrong, F.R.S.

The investigation deals first with the variations in the amount of calcium carbonate—the only basic substance usually available in soils—in the experimental plots at Rothamsted. In four of the fields which have been unmanured during a long period, the loss of calcium carbonate amounts to about 1000 lb. per acre per annum. This rate of loss is much increased on some of the manured plots; the use of ammonium sulphate and chloride, as sources of nitrogen, causes an increased loss of calcium carbonate which is equivalent to the amount required to neutralise the acid of the salts applied.

When sodium nitrate is used as a manure the rate of removal of calcium carbonate is lower than on the unmanured plots. Farmyard manure has also a similar conserving effect on the calcium carbonate in the soil. Evidence is also brought forward showing that many soils which are initially very poor in calcium carbonate retain their fertility unimpaired for many years, and even show

no decline in the small amount of base they contain, although nitrification is always going on and requires a supply of base from the soil. The authors show, from experiments with water cultures and from a consideration of the analyses of field crops, that the growing plant withdraws more acid than base from the neutral salts dissolved in the soil water, leaving behind a basic residue in the form of bicarbonate. Calcium oxalate and other organic salts in plant residues are converted by bacterial action in the soil into calcium carbonate. These two agencies restore bases to the soil in quantities approximately equivalent to their removal by nitrification, and so maintain a neutral reaction in the soil.

Zoological Society, May 2.—Dr. W. T. Blanford, F.R.S., vice-president, in the chair.—Specimens of domestic chicks to illustrate peculiarities in the hereditary transmission of white plumage: W. **Bateson.**—On *Leucosolenia contorta* (Bowerbank), *Ascandra contorta* (Haeckel), and *Ascetta spinosa* (Lendenfeld): Prof. E. A. **Minchin.** The author pointed out that the nomenclature of the Calcarea Homocœla was in a more tangled state than that of any other group of the animal kingdom, with, perhaps, the exception of the malarial parasites. Dr. Bowerbank, who founded the species, gave a diagnosis that would fit any Ascon, and his type specimens were jumbles of three or four species; consequently Prof. Minchin declared his name to be of no systematic value whatever. To Haeckel's name *Ascandra contorta,* Prof. Minchin referred a sponge extremely abundant on the Mediterranean coasts of France. Prof. Minchin preferred to name *Ascandra contorta*, H., as *Clathrina contorta*. He believed that the *Ascetta spinosa* was only an age variation of *Clathrina contorta*, not yet possessing monaxon spicules.—Anatomy of the ferret-badger (*Helictis personata*), based on a dissection of a specimen that had recently died in the society's gardens: F. E. **Beddard.**—The osteology of the Eurylæmidæ, and the question of the systematic position of this group: W. P. **Pycraft.** While agreeing with the general consensus of opinion as to the primitive character of these birds, the author held that the isolated position which they were supposed to occupy with regard to the remaining Passeres was by no means justified by facts. The pterylography, osteology, and myology of the Eurylæmidæ all tended to show that the nearest allies of these birds were the Cotingidæ. Although undoubtedly primitive, the group, Mr. Pycraft pointed out, presented a number of specialised characters, which were especially marked in the skull and muscles of the wing.

Entomological Society, May 3.—Mr. F. Merrifield, president, in the chair.—A series of *Xenarthra cervicornis,* Baly, from Ceylon, illustrating the curious structure of the antennæ of the ♂: M. **Jacoby.**—Specimens of *Tephrosia consonaria,* ab. *nigra,* and melanic examples of *Boarmia consortaria,* all from a wood in west Kent: G. T. **Porritt.** These forms were exactly on the same lines as the melanism in west Yorkshire, and it is curious they should occur in such widely separate localities. The two genera, however, are evidently prone to melanism, as Mr. Porritt had now seen black, or almost black, specimens of all the British species except *Tephrosia punctulata.*—(1) Two specimens of the very rare Staphylinid, *Medon castaneus,* Grav., taken in the Oxford district during the last week of April; (2) several examples of both sexes of the giant flea *Hystrichopsylla talpae,* Curtis, from field-mouse nests in the same district; (3) the type-specimen of the Bostrichid beetle *Dinoderus ocellaris,* Steph. (taken by the late Prof. Westwood at "Little Chelsea" previous to 1830), from the Hope collection at Oxford: Commander J. J. **Walker.**—Heliotropism in Pararge and Pyrameis: Dr. G. B. **Longstaff.**—The structure and life-history of *Psychoda sexpunctata,* Curtis: J. A. **Dell.**—The three-colour process as applied to insect photography: Dr. D. H. **Hutchinson.**

Mathematical Society, May 11.—Prof. Forsyth, president, in the chair.—The following papers were communicated:—The intersection of two conic sections: J. A. H. **Johnston.** The object of the paper is to determine the number (0, 2, or 4) of the real intersections of two real conics by means of formulæ involving the invariants, or other concomitants of the system. The discrimination depends upon the signs of the coefficients of a certain cubic equation, one root of which can be interpreted, when all the intersections are real, as the area of the quadrilateral formed by them. It is shown that one of the conditions of reality obtained by previous writers admits of very great simplification.—On a system of conics yielding operators which annihilate a cubic, and its bearing on the reduction of the cubic to a sum of four cubes: H. G. **Dawson.**—Informal communications were made as follows:—High Pellian factorisations: Lieut.-Colonel A. **Cunningham.** A method was explained for constructing very large factorisable numbers of the form y^2+1 (with complete resolution into prime factors) from the Pellian equation $y^2-Dx^2=-1$. Examples were given, among them being a number of 78 digits, viz. $(2^{128}+3\cdot2^{42})^2+1$; this was shown to be expressible as $(2^{84}+1)(2^{86}+1)^2$, for which the resolution of the factors $2^{84}+1$ and $2^{86}+1$ had been obtained by Lucas.—The stability of a loaded column: Prof. A. E. H. **Love.** When the column can be treated as a "thin" rod, and the contraction of the longitudinal filaments is taken into account, the critical length is slightly greater than that obtained by the ordinary method, due to Euler, in which this contraction is neglected. The correction of the critical length is found to be $\frac{1}{4}\pi k$, where k is the radius of gyration of the cross-section of the column about an axis through its centroid at right angles to the plane of bending.

PARIS.

Academy of Sciences, May 15.—M. Troost in the chair.—The president announced the death of M. Potier, member of the section of physics.—The permeability of glass vessels: M. **Berthelot** (see p. 88).—The propagation of musical sounds in a tube of 3 metres diameter: J. **Violle** and Th. **Vautier.** Notes of low pitch carry much better than those of high pitch, the distance at which the sound ceases to be clearly a musical note being inversely as the square root of the number of vibrations, this result being in accord with the theoretical investigations of Lord Rayleigh. From a large number of observations the conclusion is drawn that the velocity of sounds of different pitch is the same to an accuracy of 1 part in 1000.—On the menthones and menthols obtained by the reduction of pulegone by the catalytic action of reduced nickel: A. **Haller** and C. **Martine.** Pulegomenthone was obtained when the nickel was maintained at 140° to 160° C.; its physical and chemical properties are given, and there is reason to suppose that the ketone obtained is a mixture of menthones, and further work is being carried out in this direction. By slightly modifying the conditions of the reduction an additional pair of hydrogen atoms is taken up, giving pulegomenthols, two of which, in addition to ordinary menthol, were isolated from the product of the reduction.—On the constitution, saccharification, and retrogradation of potato starch: L. **Maquenne** and Eug. **Roux.** Natural starch is regarded by the authors as a mixture of two substances, distinguished by the names amylocellulose and amylopectine, possessing different reactions towards iodine and malt extract.—The basic magnesium carbonates from the Santorin eruption of 1866: A. **Lacroix.** The structure of this mineral, the quantities of which were too small for quantitative analysis, agrees with that of the basic carbonate $4MgCO_3.Mg(OH)_2.4H_2O$. As this appears to be a new species, the name of giorgiosite is proposed for it.—On the lifting power of a motor-driven helix: **Prince of Monaco.**—M. Louis Henry was elected a correspondant for the section of chemistry in the place of Prof. Williamson.—On a photographic meridian telescope for determining right ascension: Jean **Mascart** and W. **Ebert.**—On the forces giving rise to conical trajectories: Cyparissos **Stéphanos.**—On the electrostatic rigidity of gases at high pressures: Ch. Eug. **Guye** and H. **Guye.** Measurements were made of the explosive potential in gases at varying pressures. The gases studied were nitrogen, air, oxygen, hydrogen, and carbon dioxide, the pressures varying from 2 to 65 metres of mercury. Up to 10 atmospheres, the explosive potential is a linear function of the pressure, but for higher pressures the ratio of explosive potential to pressure diminishes. The results were unaffected by the presence of a radium salt.—On the effects of Foucault currents and the hysteresis of iron on oscillatory sparks: G. A. **Hemsalech.** By means of a

photographic method it has been found that the effect of Foucault currents is to augment the frequency of the oscillations per second without influencing the number of oscillations in each discharge. Hysteresis destroys the oscillations and diminishes, more or less, the frequency.—A study of the radiographic power of an X-ray tube: S. **Turchini.** The radiographic effects, as measured by the action on a photographic plate, are found to follow the same laws as the radioscopic effects, and there is reason to suppose that the radiotherapeutic effects will follow similar laws as regards the relation between efficiency and the length of the equivalent spark.—On the conductivity of the gases from flames: Eugène **Bloch.** The ions contained in the gases given off from a flame, at the end of a time sufficiently long take a mobility of the order of 0·01 mm., and hence should be classed as large ions.—On the ionisation and coefficient of magnetisation of aqueous solutions: Georges **Meslin.**—The properties of pyrrhotine in the magnetic plane: Pierre **Weiss.**—On the causes of varieties of halation in photographic plates: A. **Guébhard.**—The triboluminescence of metallic compounds: D. **Gernez.** The luminous effect observed when certain crystals are broken is not, as has been supposed, essentially a property of organic compounds, and a list of seventy-four inorganic compounds is given in which this effect has been observed.—The properties of some anhydrous chlorides of metals of the rare earths: Camille **Matignon.** Details are given of the crystalline form, colour, density, melting points, heats of solution and formation of the chlorides of lanthanum, praseodymium, neodymium, and samarium.—On a reaction of rhodium: Piñerûa **Alvarez.** Chlorine, acting on an alkaline solution of a rhodium salt, gives a characteristic blue colour, due to the formation of sodium perrhodate.—The action of the metal ammoniums on alcohols: a general method for the preparation of the alcoholates: E. **Chablay.** The alkali ammoniums, acting upon a solution of the anhydrous alcohol in ammonia, give a quantitative yield of the alcoholate.—Propionylcarbinol and its derivatives: André **Kling.**—Contribution to the study of the derivatives of benzodihydrofurfurane: A. **Guyot** and J. **Catel.**—On methæmoglobin: M. **Piettre** and A. **Vila.**—Researches on the mode of action of philocatalase: F. **Batelli** and Mlle. L. **Stern.** The name philocatalase is given to a ferment which is present in many animal tissues, although without direct action on catalase it possesses the property of protecting the catalase against the destructive action of anticatalase. The present paper deals with the mechanism of this reaction.—Researches on the comparative power of adhesion of different copper solutions employed as a remedy against mildew: E. **Chuard** and F. **Porchet.**—On a bacterial decay of cabbage: Georges **Delacroix.**—The classification and nomenclature of arable earths according to their mechanical constitution: H. **Lagatu.**—The termination of the motor nerves in the striated muscles of man: R. **Odier.**—On the problem of statical work: Ernest **Solvay.**—On the overlapping strata in the Piedmont zone: Maurice **Lugeon** and Émile **Argand.**—On an extraordinary halo: M. **Pernter.**

DIARY OF SOCIETIES.

THURSDAY, MAY 25.

ROYAL SOCIETY, at 4.30.—Croonian Lecture, "The Globulins": W. B. Hardy, F.R.S.

ROYAL INSTITUTION, at 5.—Electro-magnetic Waves: Prof. J. A. Fleming, F.R.S.

THURSDAY, JUNE 1, 1905.

PUBLIC HEALTH AND SEWAGE PURIFICATION.

Sanitary Law and Practice. A Handbook for Students. By W. Robertson, M.D. (Glas.), D.P.H., and Charles Porter, M.D., B.Sc. (Public Health), M.R.C.P. Edin. Pp. xiii+756. (London: Sanitary Publishing Co., Ltd., 1905.) Price 10*s.* 6*d.* net.

The Sewage Problem. A Review of the Evidence Collected by the Royal Commission on Sewage Disposal. By Arthur J. Martin, Assoc.M.Inst.C.E., M.R.San.I. Pp. xvi+363. (London: Sanitary Publishing Co., Ltd.) Price 8*s.* 6*d.* net.

Simple Methods of Testing Sewage Effluents. For Works Managers, Surveyors, &c. By George Thudicum, F.I.C. Pp. 60. (London: Sanitary Publishing Co., Ltd., n.d.) Price 2*s.* 6*d.* net.

THE official responsibility for the safeguarding of the public health rests mainly with the representatives of four professions, viz. the medical officer, with his colleague the sanitary inspector, the bacteriologist, the engineer, and the chemist. A study of the volumes under review has strengthened the belief that it is desirable that members of each profession, while working cordially together for a common end, should severally recognise their respective limitations.

The text-book on "Sanitary Law and Practice" by Drs. Robertson and Porter is written in sections, each section referring to some special branch of public health work. A considerable portion of each section is occupied by a digest of the legal enactments affecting the subject, this being followed by paragraphs dealing, by description and advice, with the practical duties of the health officer. The condensation of legal information, so far as can be estimated by references to special points coming under the experience of the reviewer, is done with judgment, and constitutes a feature of the book, of great value alike to the student and to the practitioner.

Many useful hints from the wide experience of the authors are to be found in the descriptive portions of the book. Their experience, however, is naturally not all-embracing, and it is not difficult to note where their information is derived from the statements of others.

The subject of destructors, although coming within the province of the engineer, is evidently one with which the authors are familiar. The descriptions are clearly written, and the essential points in construction, choice of site, and proper management well brought out.

In the section on food and drugs no attempt is made to instruct the medical officer in duties which properly belong to the public analyst. This is satisfactory in view of the attempt frequently made by small authorities to combine the offices of public analyst and medical officer. Even in such a comparatively simple matter as the analysis of a sample of water, which in the chapter on water supply (p. 433) is referred to as part of the medical officer's duties, unsuspected pitfalls may lurk. It is doubtful whether bacteriological examinations should ever be undertaken by any but a trained bacteriologist, at any rate where identification of a given species is required.

In the section on disinfection a questionable prominence is given to the use of sulphur. The authors themselves, in a later paragraph, deprecate the use of superheated steam as being "no better than a gas," and in view of the obvious disadvantages in the use of sulphur, which have given rise to serious complaint of destruction of fabrics and fittings, especially on board ship, it can hardly be compared with liquid disinfectants such as formalin. No reference is made to the use of hypochlorites, which in certain circumstances have been found to give excellent results.

A wise reserve is maintained on the vexed question of sewer ventilation, a qualified approval being given to upcast shafts. It is unfortunate that a similar reserve has not been exercised in the chapter on sewage purification. In a book intended for students it is unwise to select, even for description, any form of patented appliance which is not thoroughly established. The choice for special commendation of one particular patented apparatus, concerning the merits of which competent opinion can at least be said to be divided, is certainly to be deprecated. A clear exposition of general principles of sewage treatment would have been more valuable.

This leads to the consideration of the able condensation of the bulky volumes of evidence given before the Royal Commission on Sewage Disposal which is to be found in Mr. Martin's book on the "Sewage Problem." Mr. Martin has provided a book which will be eagerly sought after by members of sewage committees and others who are appalled at the mass of matter in the numerous blue-books published by the commission. He is to be congratulated upon the impartial way in which he has marshalled the evidence. Possibly because of this impartiality the impression left upon the reader is that in spite of the great amount of work that has been done on the subject, sewage purification is still rather an art than a science.

The Royal Commission has been criticised for the slowness of its methods. A more just criticism would be that it might have devoted more energy to questions affecting the theory of the processes in use. As it is, a mass of empirical and sometimes conflicting information has been accumulated, from which it is extremely difficult to extract underlying certainties. While fully realising that a large part of the sewage problem is concerned with purely practical questions of cost and local conditions, yet ultimately the economic solution must depend on a full knowledge of the changes taking place in the course of various methods of treatment; and these are as yet by no means perfectly understood. It is curious, *e.g.*, that no witness deals in any detail with the purely physical effects produced by contact with the filtering medium, although many observers, especially on the Continent, believe that these play a very large part in connection with the changes produced. It is by no means

certain even yet that anaërobic action is absolutely necessary at any stage of sewage purification. Many other equally important questions might be instanced on which knowledge is still extremely limited.

The outstanding result of the Royal Commission's labours which will most appeal to local authorities is the statement that adequate purification can be effected without land treatment, which, if recognised by the Local Government Board, will remove what is, in many cases, an impossible restriction. Their recommendation in regard to a central controlling and advisory authority, if resulting in the creation of a department similar to the Massachusetts Board of Health, may prevent great waste of public money. Such a board might exercise wise discretion as to the amount of purification necessary under given conditions. No central control, however, can be effective without efficient local management, and Mr. Thudicum's little book of simple methods of sewage analysis will be of great assistance to local engineers and intelligent works managers, and will help to lighten the work of the trained specialist, with whom the solution of difficulties ultimately rests. G. J. F.

AN AMERICAN CONTRIBUTION TO ARCHÆOLOGY.

University of Pennsylvania: Transactions of the Department of Archaeology: Free Museum of Science and Art. Vol. i. Parts i. and ii. Pp. 125. (Published by the Department of Archæology, 1904.)

THE most important article in this volume is the description of the American excavations at Gournià, in Crete, which have already been referred to in the pages of NATURE (September 15, 1904, p. 482). Miss Harriet A. Boyd, the leader of the expedition, gives a full and very interesting description of her work, illustrated by photographs which give the reader a very good idea of the beautiful scenery of the Gulf of Mirabello (well bestowed name!), on the shores of which she found her work. No more delightful spot for archæological exploration could be imagined. Leaving the rather arid and uninteresting Candiote shore, near which Knossos lies, dominated by the towering hill of Iuktas, on the top of which, so legend says, the god Zeus died and was buried, the traveller skirts the base of the Lasithiote mountain-mass and reaches the narrow isthmus of Hierápetra (the ancient Hierapytna). Before him rises a magnificent rocky wall of mountain, Thriphte by name, behind which is the peak called the Aphendi, or Lord of, Kavoúsi, the village which lies at its foot. This wall is rent by a mighty cleft, the chasm of Thriphte, which is one of the dominating features of the landscape. Along the base of the wall runs the high-road from Kavoúsi to Hierápetra across the isthmus, which is low-lying land, forming a complete break in the mountain-backbone of Crete. On the northern shore of the isthmus is a good beach, Pachyammos ("Deep-sand") by name; in the centre of it the traveller will see a large white house.

This was Miss Boyd's headquarters. All around are splendid mountains and "a coast-line as picturesque as any in Southern Europe," to quote her description, which is not exaggerated; she might have said "more picturesque than," with reason. Away to the left are the snowy heights of Lasíthi, the hills above the *skála* or landing-place of Ayios Nikólas, and distant rocky Spinalonga, still the home of a peculiar race of Mohammedan fishermen—corsairs not so very long ago. To the right is the little isle of Psyrà, swimming in the blue water. One would think that the excavators on the monotonous plains of Babylonia, whose doings are chronicled by Prof. Hilprecht in the last contribution to this volume,[1] would have given much sometimes to have been able to transport themselves for a brief space to such goodly surroundings!

Pachyammos lies a mile or so beyond, and east of, the scene of Miss Boyd's work, the low hill of Gournià, on which she has discovered the remains of a "Mycenæan," or more correctly "Minoan," town, a Bronze age settlement. It is a small Pompeii. One can walk up the sinuously curving little main street and look right and left into the ruined houses of the Bronze age "Minoans." There is even a sort of court-house or "palace," to give it the stereotyped appellation, with its right-angle of low steps quite on the model of the splendid right-angled stairways of Knossos and Phaistos, which Dr. Evans considers to have been theatres, the prototypes of the stepped Greek theatres of the classical period. This "palace" must have been the official centre of the town. Formerly, judging from classical analogies, one talked of a prince or "dynast" ruling from every one of these little palaces over his own little πόλις or city-state; but it will probably eventually be found that the ruler who lived in such a "palace" as that of Gournià was no more than a mere mayor or demarch, a member of an official bureaucracy analogous to that of ancient Egypt, dependent upon the metropolitan authorities at Knossos. It becomes more and more probable that Crete in Minoan days was a homogeneous and highly organised State like Egypt, not a mere congeries of a hundred warring villages, as in classical times.

The official centre was not the religious centre of the town. The cathedral of Gournià stood in the middle of the town, and was approached by a special street of its own.

"Not imposing as a piece of architecture," writes Miss Boyd (p. 41), "it is yet of unique importance as being the first 'Mycenæan' or 'Minoan' shrine discovered intact. The worshipper ascended three steps and through a doorway 1.50 m. wide entered an enclosure, about 3 m. square, surrounded by walls half a metre thick and 50 to 60 cm. high. The floor is of beaten earth."

The more noteworthy of its contents are

"a low earthen table, covered with a thin coating of plaster, which stands on three legs and possibly served as an altar, four cultus vases bearing symbols of Minoan worship, the disc, consecrated horns and double-headed axe of Zeus, a terra-cotta female idol entwined with a snake, two heads of the same type as

[1] Very curiously described as "A Lecture delivered before German Court and University Circles, by H. V. Hilprecht." In it Prof. Hilprecht tells us little or nothing about the excavations at Nippur that has not already appeared in his "Explorations in Bible Lands," and the photographs published are already well known to archæologists.

the idol, several small clay doves and serpents' heads, all of coarse terra-cotta, and a fragment of a pithos, on which a double-axe and disc are modelled in relief."

This important find has since been paralleled by Dr. Evans's discovery at Knossos of a similar shrine of the snake-goddess with fine glazed faïence figures, referred to in NATURE (vol. lxx. p. 482). But Miss Boyd was the first to discover the Minoan snake-goddess, of whose existence we had no inkling before the excavations at Gourniâ.

Another good find, of which Miss Boyd gives a fine facsimile plate, was the head of a bull in terra-cotta, a typically "Mycenæan" object, paralleled by the famous silver bull's head found by Schliemann at Mycenæ, and the Egyptian representations of golden *protomae* of bulls being brought as gifts to the court of Thothmes III. by the Mycenæan (or rather "Minoan") ambassadors from "Kefti" (Crete).

Miss Boyd's work has contributed results to Mycenæan lore which are of the highest importance, results upon which the officers of the American Exploration Society at Philadelphia, which dispatched her expedition, are to be heartily congratulated.

Modern Electric Practice. Vol. v. Edited by M. Maclean, Pp. vi+287. (London: The Gresham Publishing Co., 1904.) Price 9s. net.

Electricity Control: A Treatise on Electric Switch-Gear Systems of Electric Transmission. By Leonard Andrews. Pp. xv+231. (London: Chas. Griffin and Co., Ltd., 1904.)

THE electrical engineer who wishes to keep pace with the development of his profession and desires to know something more than that which concerns only the particular branch in which he is engaged has a very hard task before him at the present day. He must, in the first instance, endeavour to keep an eye on the technical literature—the innumerable journals and proceedings, the monthly magazines, and the weekly papers—of at least four countries in three different languages. This is in itself a task of no mean difficulty, which is heightened rather than diminished by the various "abstracts" available. So rapid is the multiplication of journals and papers that one is tempted to think that the best advice to give a student would be to read nothing, as if he tries to read much he will waste more time over what is of no value to him than he will spend wisely on the one useful article in a thousand; one is tempted still more to wish that a rigorous technical censorship might be instituted which would allow nothing to find its way into print but that which was of permanent value to the world. In this way the amount of technical literature might be brought within reasonable limits by being reduced to, say, one-tenth of its present volume.

If this is true of the matter which is published in journals—which has, at least as a rule, the merit of originality—it is still more true of the matter which appears in the form of technical text-books. We imagine these books find a ready sale, else we cannot account for their publication; yet we do not know by whom they are read except the reviewers. This is exemplified by the six volumes before us, all of which have appeared within the last few months. With the exception of the first two, we would venture to say that it would have been just as well, and possibly even better, had they not been published. We do not mean thereby that they are bad books, though one of them we think, should not be left about where young electricians might see it; but they are not of merit enough to justify the expense of their publication or purchase.

Take, for example, Miss Zimmern's little volume; it is tastefully bound and clearly printed on good paper—there is something in its appearance strongly suggestive of a book of minor poetry. Add to this that it is pleasantly written and that there is nothing very seriously wrong with its statements, and its merits are summed up. On the other hand, we are confident that it would fail in its object of explaining the complex theories of modern electricity to the "general reader"; he might put down the book with the feeling that his knowledge had been increased, but it would be a mistaken notion. It requires genius of a very rare kind, such as was shown by Faraday in his "Chemical History of a Candle," or by Prof. Perry in his "Spinning Tops," to write a book of this kind; we intend no disparagement to the writer of this volume by saying that such genius is not shown in it.

Messrs. Henry and Hora's volume is of another stamp; in a preface which reads like a publisher's advertisement, the authors state that "the work will be found eminently practical, scientific, and accurate." We have found it quite the reverse, and feel sorry for the "apprentice" or "artisan" who "gains a complete knowledge of the fundamental principles of electricity" from its pages. This is a book which no self-respecting electrical censor, however lenient, would have allowed to appear in print.

The two last books on the list are not without merit or value, but it is at best of an ephemeral kind. Of "Modern Electric Practice" we have already expressed our views in writing of the previous volumes; the present one does not depart from the same high standard in production, and the three articles in section iv., dealing with boilers, engines, and auxiliary plant, are well written and well illustrated. The article on electrochemistry and electrometallurgy is less satisfactory. We must confess, however, that the inaccuracies noticed in previous volumes make us, unjustly perhaps, suspicious of the figures and data in the one be-

fore us. Mr. Andrews's book on "Electrical Control" is a descriptive treatise on switch-gear. It possesses the same disadvantages as "Modern Electric Practice"; one cannot learn electrical practice from a book; there is only one school—the practical school—in which one can learn the principles and details of construction of apparatus in one-tenth of the time and ten times as thoroughly as by means of written descriptions. Practical men are apt to complain that text-books are valueless, as they are written by theorists; we have read a great many text-books of late written by practical men, and have come to the conclusion that it is only the theorist who should write them. He can describe the underlying principles which persist when the fashion of their application alters; the practical man describes the methods of his practice which even as he writes become antiquated.

We have reserved to the last the two volumes which head our list. Messrs. Poincaré and Vreeland's book deserves a place in any electrical library on account of its remarkably simple and lucid explanation of Maxwell's theory and of the work of Hertz, Lodge, and others which led to the development of Hertzian telegraphy. This is from the pen of M. Poincaré, translated by Mr. Vreeland, and forms the first part of the book. The second part, written by Mr. Vreeland, deals with the problems presented by the practice of wireless telegraphy, and the writer, by wisely confining himself to principles rather than details, has succeeded in writing a worthy sequel to M. Poincaré's work.

Mr. Russell's book is the first volume of a mathematical treatise on alternating currents. Alternating current machinery is growing so steadily in importance, and the mathematical theory in connection with it is so complex, that there is plenty of room for a thorough and comprehensive work of this kind. The present volume deals with the general theorems, and the second will be devoted to the more specific theory of alternating current machines and the transmission of power.

MAURICE SOLOMON.

OUR BOOK SHELF.

Vegetationsbilder. Edited by Dr. G. Karsten and H. Schenck. Second series. Parts i.—viii. (Jena: Gustav Fischer, 1904.)

THE first series of the "Vegetationsbilder" met with well-merited success, and a second series has been appearing at intervals during the past year. Of the contributors to the first series, Drs. G. Karsten and E. Stahl have again supplied material, the former taking up a never-failing source of interest in the mangrove vegetation, whilst Dr. Stahl, in a double part, deals with the xerophytes and conifers of Mexico; amongst the latter the primeval Taxodium trees growing in the park of Chapultepec and the sombre cypresses on the road to the sacred mount of Amecameca bear the impress of historic antiquity. Another number, consisting of parts v. to vii., is devoted to the representation of mid-European forest trees, in accordance with an expressed desire for subjects taken from native sources. The photographs taken by Dr. L. Klein include typical specimens of conifers and beeches in the Schwarzwald and Switzerland, and others showing the changes wrought by browsing animals and devastating winds; many of them are excellent, notably a scene of wind-blown pines which have been entirely cleared of branches except to leeward, but similar subjects are accessible to most botanists, and for this reason they do not possess the interest attaching to photographs from less accessible countries. The names of several new contributors are announced, among them Mr. E. Ule, whose character sketches of epiphytes in the Amazon region of Peru appear in the first part of this series. Of the Cactaceæ, which are widely spread through South America, a number of genera include epiphytic species, and in this region Cereus is predominant. *Cereus megalanthus*, a species which might be called a climbing epiphyte, is shown perched on a Ficus tree. Another curious condition is that of a flourishing bromeliad, *Streptocalyx angustifolius*, where, according to the writer, the exuberance of vegetation is so directly traceable to ants that he compares the phenomenon with the fungus gardens described a few years ago by Dr. A. Moeller. The last part of the series contains photographs taken in the Italian colony of Eritraea by Dr. Schweinfurth. *Hyphaene thebaica*, the doum palm, familiar on account of its branching habit, the sycomore fig, and an arboreous Euphorbia are among the characteristic specimens chosen to illustrate different regions in the country.

Author and Printer. An Attempt to Codify the best Typographical Practices of the Present Day. By F. Howard Collins. Pp. xv+408. (London: Henry Frowde, 1905.) Price 5s. net.

THE want of uniformity of spelling, capitalisation, punctuation, and use of italic type causes continual trouble to all who are responsible for the editorial supervision of scientific literature in any form. Some authors are more German than the Germans in their use of capitals, while others underline their manuscripts as freely as ladies do their correspondence. It is frequently difficult to decide questions of orthography, and to reduce individual practice to the consistent style, which is desirable in the columns of a periodical, but is not always maintained. Mr. Collins has prepared his book to help in this end, as a standard guide for "Authors, Editors, Printers, Correctors of the Press, Compositors, and Typists."

The volume contains more than twenty thousand separate entries of words arranged alphabetically. Included among these are abbreviations, disputed spellings, foreign words and phrases, divisions of words, and various rules and explanations which should prove of service to authors and editors. The proofs of the work have been read by many writers and others who can give authoritative opinions as to what is correct or customary, so that the book does not contain merely Mr. Collins's decisions, but a consensus of opinion edited by him.

Highways and Byways in Derbyshire. By J. B. Firth. With illustrations by Nelly Erichsen. (London: Macmillan and Co., Ltd.) Price 6s.

WITH this book as a guide, a tourist could spend many pleasant weeks in Derbyshire, and he would learn that every part of the county has literary and historical associations of great interest. But while the human side is so well represented, little notice is taken of nature, except from the æsthetic point of view. "Of natural history and geology," says the author, "there is frankly nothing in this book, of science nothing, of sport nothing."

Notwithstanding this confession of what we may be permitted to describe as sins of omission, notes and descriptions of places in which scientific readers are particularly interested occur here and there. For instance, a short account is given of the stone circle of Arborlow, the Stonehenge of the Midlands. The monument consists of a circular enclosure in which are a number of blocks of limestone, all lying flat on

the ground in a rude circle, while at the centre are large blocks which probably formed the central dolmen. "There are two entrances to the enclosure, a northern and a southern, and on the east side of the latter is a large detached mound. Four hundred yards west of the main enclosure is a still larger mound, known as Gib Hill, connected with it by a low rampart of earth, now nearly worn away." Buxton and Matlock lead Mr. Firth to make some quotations from Erasmus Darwin's poetical references to them in his "Botanic Garden: Economy of Vegetation," and "Loves of the Plants." Dr. Darwin knew and loved the scenes he described, whatever opinion may be held as to his possession of the divine afflatus. There are a few other references to people and scenes of especial interest to the scientific world, but the book will not be valued for these so much as for its bright narrative of literary and historical centres of Derbyshire, and its fine illustrations.

The Tower of Pelée. New Studies of the Great Volcano of Martinique. By Prof. Angelo Heilprin. Pp. 62+xxii plates. (Philadelphia and London: Lippincott, 1904.)

PROF. HEILPRIN'S latest volume on Martinique is chiefly remarkable for the beautiful photographic plates with which it is illustrated; they give an excellent idea of the features of the great tower of solid lava which for nearly three years has been the centre of interest in the crater of Pelée. One of these plates, however (No. xi), seems to have been accidentally printed upside down. In the accompanying text there is an account of the author's fourth visit to the volcano in June, 1903, and a good deal of somewhat discursive matter regarding the lessons to be learnt from the recent eruptions. The number of points which are still unsettled concerning the mechanism of the explosions and the concomitant phenomena is very large, and the author shows a wise caution in dealing with some of them. He advances the opinion that the tower of Pelée is a volcanic core of ancient consolidation, and not an extrusion of solidified new lava, as the French observers believe. We cannot believe this is at all likely to obtain general acceptance. J. S. F.

Experimental Researches on the Flow of Steam Through Nozzles and Orifices. By A. Rateau. Translated by H. Boyd Brydon. Pp. iv+76. (London: Constable and Co., Ltd., 1905.) Price 4s. 6d. net.

THE laws of flow of steam are of much importance in the design of turbines. A clear sketch is given of the theory, and then an account of an excellent experimental research to determine the values of the constants. Amongst previous experiments, those of Napier are English, not American as the author states. The novelty in M. Rateau's method is the use of an ejector condenser for condensing the steam. The rise of temperature, which is easily measured, gives the quantity of steam condensed. The errors of the method, especially that due to entrained water, are carefully examined. Convergent nozzles and a thin plate orifice were used. The results are compared with those by Hirn on air, and close agreement is found. In a note, the complex phenomenon of the discharge of hot water just on the point of evaporating is examined.

The translation is clear. It is, however, a defect, for English readers, that the principal formulæ are left as given by the author in foreign units. The book is essentially one for practical use, and it would have added much to the convenience of engineers if other formulæ than the one on p. 6 had been given in English units.

Introductory Mathematics. By R. B. Morgan. Pp. vi+151. (London: Blackie and Son, Ltd., 1905.) Price 2s.

IN Mr. Morgan's "Introductory Mathematics" the view of the author is that as soon as a boy knows decimal and vulgar fractions he should begin a mixed course of elementary practical mathematics comprising algebra, geometry, and squared-paper work, developed as a whole in mutual dependence, leading up through the manipulation of formulæ to the solution of problems involving simultaneous simple equations and giving a knowledge of the fundamental facts of geometry with a training in practical applications such as the plotting of graphs and of figures to scale, and the finding of simple areas and volumes. This scheme, ignoring the old water-tight compartment system, is a good one. The chapters on algebra and geometry usually alternate, and the work progresses on natural and easy lines, with illustrations of every-day interest. The author might with advantage have carried the idea still further and have brought in computations from quantitative experimental work in the laboratory, involving the use of the balance and measuring flask, and perhaps an investigation of the action of forces at a point. There are some minor defects, such as an occasional lack of precision in a statement, bad perspective in several of the figures, the use of a graph to give a forecast of population fifty years hence, &c. But the treatment of the subject as a whole is very satisfactory; there is a good collection of exercises, and the book is well suited to its purpose.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Dynamical Theory of Gases and of Radiation.

LORD RAYLEIGH, in a letter which appears in NATURE of May 18, opens up the general question of the applicability of the theorem of equipartition to the energy of the ether. As the discussion has arisen out of my "Theory of Gases," may I, by way of personal explanation, say that although I was fully alive to the questions referred to in this letter when writing my book, yet it seemed to me better not to drag the whole subject of radiation into a book on gases, but to reserve it for subsequent discussion? Since then I have written two papers in which questions similar to those raised by Lord Rayleigh are discussed from different aspects, but as neither of these papers is yet in print, I ask for space for a short reply explaining how my contentions bear on the special points raised by Lord Rayleigh's letter.

May I, in the first place, suggest that the slowness with which energy is transferred to the quicker modes of ether-vibration is a matter of calculation, and not of speculation? If the average time of collision of two molecules in a gas is a great multiple N of the period of a vibration, whether of matter or of ether, then the average transfer of energy to the vibration per collision can be shown to contain a factor of the order of smallness of e^{-N}. The calculations will be found in §§ 236–244 of my book. It is on these that I base my position, not on a mere speculation that the rate of transfer *may* be slow. Lord Rayleigh's example of a stretched string, say a piano wire, will illustrate the physical principle involved. If a piano hammer is heavily felted, the impact is of long duration compared with the shortest periods of vibration, so that the quickest vibrations are left with very little energy after the impact, and the higher harmonics are not heard. If the felting is worn away, the impact is of shorter duration, the higher harmonics are sounded, and the tone of the wire is "metallic."

The factor e^{-N} is so small for most of the ether-vibrations as to be negligible. There is no sharp line of demarcation between those vibrations which acquire energy

very slowly and those for which the rate is appreciable; but as e^{-N} varies rapidly with N when N is large, there will be but few vibrations near the border, so that it seems legitimate, for purposes of a general discussion, to divide the vibrations into the two distinct classes, quick and slow, relatively to the scale of time provided by molecular collisions.

When the material bodies are solid, the physical principle is the same, the relatively slow motions of the atoms affecting the "quick" vibrations of the ether only by raising a sort of "equilibrium tide."

The number of "slow" vibrations of the ether in any finite enclosure is finite. These quickly receive the energy allotted to them by the theorem of equipartition. Thus they form the medium of transfer of radiant energy between two bodies at different temperatures. After a moderate time the slow vibrations have each, on the average, energy equal to that of two degrees of translational freedom of one molecule; the quick vibrations have no appreciable energy, while the intermediate vibrations possess some energy, but not their full share. It is easily seen that the number of slow vibrations is approximately proportional to the volume of the enclosure, so that roughly the energy of ether must be measured per unit volume in order to be independent of the size of the enclosure. For air under normal conditions, I find as the result of a brief calculation that this value is of the order of 5×10^{-9} times that of the matter. The law of distribution of this energy will be

$$\theta\lambda^{-4}d\lambda$$

until we arrive at values of λ which are so small as to be comparable with

$$\text{radius of molecule} \times \frac{\text{velocity of light}}{\text{velocity of molecule}}.$$

After these values of λ are passed, the formula must be modified by the introduction of a multiplying factor which falls off very rapidly as λ decreases, and which involves the time during which the gas has been shut up. It is easily found (*cf.* "The Dynamical Theory of Gases," § 247) that at 0° C. the spectrum of radiant energy is entirely in the infra-red; at 28,000° C. it certainly extends to the ultra-violet, and probably does so at lower temperatures.

Finally, Lord Rayleigh asks:—

"Does the postulated slowness of transformation really obtain? Red light falling upon the blackened face of a thermopile is absorbed, and the instrument rapidly indicates a rise of temperature. Vibrational energy is readily converted into translational energy. Why, then, does the thermopile itself not shine in the dark?"

Before trying to answer this, I wish to emphasise that my position does not require the *forces* of interaction between matter and ether to be small. Considering a gas for simplicity, the transfer of energy per collision to a vibration of frequency p is found to be proportional to the square of the modulus of an integral of the form (*cf.* "The Dynamical Theory of Gases," § 237)

$$\int f(t)e^{ipt}dt,$$

where $f(t)$ is a generalised force between matter and ether. The integral may be very small either through the smallness of $f(t)$ or the largeness of p. I rely entirely on the largeness of p, because calculation shows this to be adequate. The thermopile experiment gives evidence as to the magnitude of $f(t)$, but this does not alter the fact that the integral is small for large values of p.

This being so, I am afraid I do not very clearly understand why the thermopile should be expected to shine in the dark. If the red light is a plane monochromatic wave, its energy represents only two coordinates of the ether, and has to be shared between the great number of coordinates, six for each atom, which belong to the thermopile. If the red light comes from a large mass of red-hot matter inside the same enclosure as the thermopile, then the thermopile will soon be raised to the temperature of this mass, and *may* shine in the dark. If the hot mass consists of iron, say at 600° C., the atomic motions in the iron must be sufficiently rapid to excite the red vibrations in the ether. But if the face of the thermopile is of lampblack, the atomic motions in lampblack at 600° C. may not be of sufficient rapidity (mainly, so far as can be seen, on account of the lower elasticity of the material) to excite red vibrations except as a kind of "equilibrium tide," in which case the lampblack will not emit red radiation.

I cannot ask for further space in which to answer Lord Rayleigh's point as to the enclosure with a hole in it, but I have discussed a similar question in a paper which I hope will soon be published, in connection with Bartoli's proof of Stefan's law. I hope that this paper, and a second one which is at present in the hands of the printer, will explain my position more clearly than I have been able to in the short limits of a letter.

May 20. J. H. JEANS.

Fictitious Problems in Mathematics.

I HAVE to thank your reviewer for so readily supplying (NATURE, May 18, p. 56) the example to prove his contention—and which appears (to me) to disprove it.

The man who set that example did so in order to test (*inter alia*) whether the pupil knew that, for any friction to arise, both the surfaces must be rough; your reviewer originally wrote:—"What the average college don forgets is that roughness or smoothness are matters which concern *two surfaces* not *one body*." The italics are your reviewer's; and this is the statement which I called (and still call) in question.

It is no part of my book to uphold the verbiage in which the example is couched; by chance, in my former letter, I explained in anticipation the terms used in it. I do not see, however, why your reviewer applies the favourite word inaccurate to these terms. Perfect smoothness may not occur in nature; still, in considering the pendulum, I probably begin by assuming no friction on the axis of suspension, and, if I try afterwards to apply a correction for this friction, I probably make an assumption which is inaccurate. Friction = pressure × a constant is inaccurate, statically and dynamically.

C. B. CLARKE.

As I take it, the mathematician's "perfectly rough body" means a body which never by any chance slips on any other body with which it is placed in contact, similarly the "perfectly smooth body" is supposed never to offer any tangential resistance to any other body which it touches. The inconsistency of this nomenclature is evident when we imagine the two bodies placed in contact with each other, as in the case of the perfectly rough plank resting on the smooth horizontal plane. The subsequent course of events cannot at the same time be compatible with the assumed perfect roughness of the one body and the assumed perfect smoothness of the other. The coefficient of friction between two bodies depends essentially on the nature of the parts of the surfaces of both bodies which are in contact as well as on their lubrication, and neither body can be said to have a coefficient of friction apart from the other. It is equally incorrect to speak of perfect smoothness or perfect roughness as attributes of a single body. Moreover, this misleading language is quite unnecessary; it is very easy to frame questions in a way that is free from objection. For instance, "A man walks without slipping along a plank which can slip without friction on a horizontal table." Or again, "A sphere is placed in perfectly rough contact with the slanting face of a wedge whose base rests in perfectly smooth contact with a horizontal plane."

G. H. BRYAN.

A New Slide Rule.

IN the article which appeared on p. 45 of NATURE, May 11, describing the Jackson-Davis double slide rule, you notice one little fault in the rule sent for examination.

We desire to exonerate the designer of the instrument, Mr. C. S. Jackson, from responsibility for the very obvious fault to which you allude, viz. that the scale on the feather edge is divided into inches and sixteenths, and that the continuation scale which is read below the ordinary slide

is in millimetres. The rules can be supplied with the plain scales either in inches or millimetres, and in the specimen submitted to you the mix up is the result of accident, and not perversity.

JOHN DAVIS AND SON.

All Saints' Works, Derby, May 20.

THE LOWER VERTEBRATES.[1]

"EVERYTHING comes to him who waits"! Certainly the patience of many has been sorely tried by the long advent which has preceded the appearance of this last volume of the Cambridge Natural History. Students of the lower vertebrates will be naturally predisposed to accord it a favourable reception, inasmuch as its predecessors have presented such a high standard of excellence. If in some respects a closer acquaintance reveals some cause for complaint it will be admitted that, surveyed as a whole, both authors and editors alike are to be congratulated on having produced a work of sterling merit.

The groups dealt with in this volume are not only of the highest scientific interest and importance, but they present more than ordinary difficulties to be investigated, and these difficulties are materially increased when stern necessity compels the several contributors to condense their work within the smallest possible limits. Happily this task has fallen on the right shoulders, and all must admire the way in which it has been performed.

The first chapter of this book has been written by Dr. S. F. Harmer, and deals with the Hemichordata, a group which includes creatures of the existence of which the layman has never heard! Yet their importance in the scheme of evolution is of the highest, inasmuch as they bridge the gap for us between vertebrates and invertebrates.

The true nature of these worm-like and tubicolous animals has been determined only after the most laborious and painstaking research, in which Dr. Harmer, the author of this chapter has borne a very conspicuous share. Though the vertebrate affinities of the worm-like Balanoglossus were first hinted at by Kowalewsky in 1866, it was not until 1886 that this relationship was really demonstrated: a triumph achieved by Bateson. Forming at first a branch by itself of the vertebrate phylum, Balanoglossus has since lost something of its unique character by the discovery that certain other tubicolous forms—Rhabdopleura and Cephalodiscus—would have to be promoted to share this position, though to the ordinary observer nothing could be less like a vertebrate in appearance! This advance in our knowledge was made by the author of this chapter; and he has now still further extended the boundaries of this group so as to include Phoronis, an animal hitherto referred both to the Gephyrea and to the Polyzoa.

Although our knowledge of the Tunicates—those "common objects of the sea-shore," known as the "sea-squirts"—has been accumulating for something more than two thousand years, it was not until the middle of the eighteenth century that any real progress in the study of these creatures was made. And yet a century passed before the appearance of Kowalewsky's epoch-making work, which showed conclusively the astonishing fact that these shapeless jelly-bags were really kith and kin of the vertebrates—but degenerates!

No other group of animals is so all-embracing in the nature of the phenomena it displays. As the author remarks, "They demonstrate both stable and variable species, monophyletic and polyphyletic groups. They exhibit the phenomena of gemmation and of embryonic fission, of polymorphism, hibernation, alternation of generations, and change of function. They have long been known as a stock example of degeneration; but in fact they lend themselves admirably to the exposition of more than one 'chapter of Darwinism.'"

Prof. Herdman has made this group peculiarly his own, and the editors are to be congratulated in having secured him to write this chapter. Nowhere else will the student find so complete and altogether admirable a summary of this most difficult and puzzling group of animals.

In dealing with amphioxus Prof. Herdman has been hampered by lack of space. This seems evident, not from the absence of any essential facts in his account, but from the condensed fashion in which the facts are presented. To the majority of those who will use this book this is perhaps of no great moment, but others, we imagine, will fail to appreciate the full importance of some phases in the life history of this "weed in the vertebrate garden."

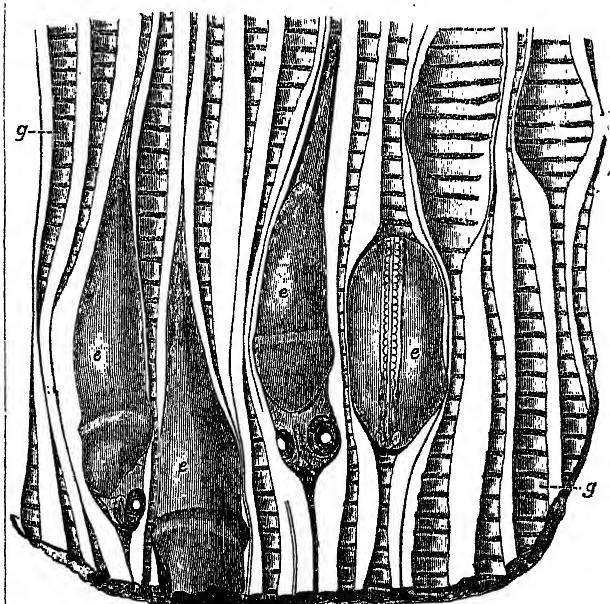

FIG. 1.—Embryos of *Rhodeus amarus* in the gill-cavities of Unio. *e*, Embryos; *g*, inter-lamellar cavities. From the "Cambridge Natural History."

The remarkable ciliated condition of the embryonic and early larval stages is, for example, all too lightly passed over. Attention is not called to the importance of the fact that in the free-swimming, ciliated larva we have a connecting link between vertebrates and invertebrates. His reference to the existence of cilia is of the briefest. He remarks simply, that "the embryonic stages being passed through during the night . . . the larva hatched in the early morning," and then, on the next page, continues, "The epiblast cells become ciliated all over the surface, so that the embryo rotates within the thin covering which still surrounds it." Passing on to describe the metamorphosis of the embryo he goes on to say that "When it has (developed) about five pairs of mesoblastic somites, it breaks out of its covering, and becomes a free swimming larva." Probably no living biologist knows more of amphioxus than Prof. Herdman. Thus, then, this lack of emphasis of a really important feature must be attributed to the fact that he had to

[1] "Hemichordata, Ascidians and Amphioxus, Fishes." By Drs. Harmer, Herdman, Bridge and G. S. Boulenger. The Cambridge Natural History, vol. vii. Pp. xvii+760. (London: Macmillan and Co., Ltd., 1904.) Price 17s. net.

compress his account unduly. As a matter of fact the whole history has been crowded into something less than eight and twenty pages, including illustrations!

This condensation is evident throughout each of the chapters so far noticed, and probably accounts for the absence of anything in the shape of an historical review of the evolution of our knowledge of these obscure groups. Surely this is to be regretted, inasmuch as this is a volume which will serve as the main source of information for many generations of students; and it would be well to place before them some idea of the laborious and patient work which has been spent by others in building up the knowledge which is theirs to-day. Such a review would serve a double purpose. It would keep alive the memory of those whose names are all too soon forgotten, and it would serve as an incentive to further work.

Probably this survey would not have been wanting, but for the fact that some two hundred and eighty of the seven hundred and twenty-seven pages which make up the book are devoted to the introduction on fishes! This is not as it should be; on this account serious

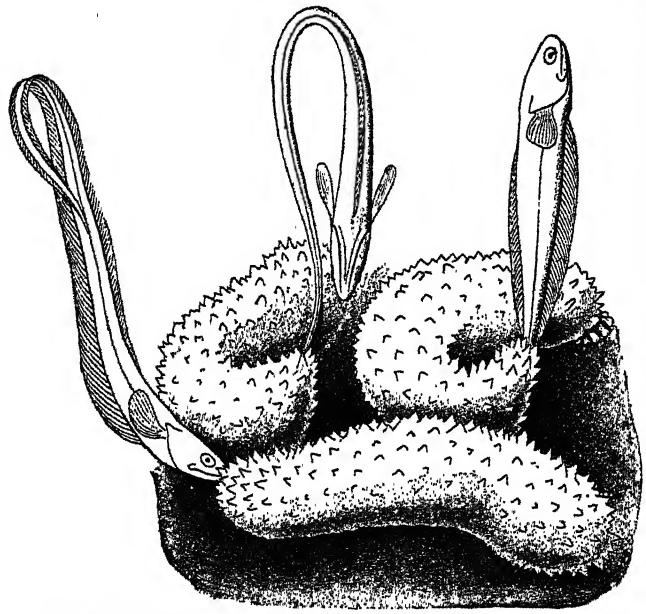

FIG. 2.—*Fierasfer acus* penetrating into Holothurians; two-fifths natural size. From the "Cambridge Natural History."

injury has been done both to the chapters which precede it and those which follow. Much of this introduction could have been dispensed with, inasmuch as matters of a purely physiological import are now included, and these are outside the scope of this volume. Lengthy as it is, it is yet incomplete. Morphological questions that should have found a place here are either ignored or dismissed in a few lines. If these had taken the room of the matter to which we object some justification might have been pleaded for the condensation of the exceedingly valuable chapters which we have just noticed. Yet, in spite of these drawbacks, this introduction will prove most valuable to those who use this volume as a text-book, and there is no doubt but that it will be widely read and highly valued in the various science schools throughout the kingdom.

It is a pity that more figures of larval fishes were not given in this introduction, designed to illustrate the remarkable transformations which some species especially undergo from the time of hatching to maturity.

In regard to the Cyclostomata it is curious that no mention is made of the extraordinary slime-secreting powers of the Myxinoids. True, he refers to "a row of mucous secreting sacs along each side of the body," but this scarcely does justice to the case; inasmuch as an instance is on record of a single individual which, placed in three or four cubic feet of water, converted the whole into a jelly-like mass, which could be lifted out with a stick! The specific name of *Myxine glutinosa* has reference to the old belief that the fish possessed the power of turning water into glue.

Prof. Bridge solves the difficulty as to the systematic position of Palæospondylus by placing them in a sort of limbo designated an "appendix to the fishes."

In this same appendix it is somewhat surprising to find not only the Ostracoderms, but the Arthrodira! As touching the former Prof. Bridge may claim that he errs, if erring he is, in good company, since so eminent an authority as Dr. Smith Woodward refuses to admit these "bones of contention" into the class Pisces. But we object to the hesitancy displayed by Prof. Bridge; he will neither call them fishes nor allow them to rank as a separate class (Agnatha), as Dr. Woodward has done. But surely there can be no question as to the class, at least, to which the Arthrodira belong? According to the most recent views they are to be regarded as Dipnoans.

In spite of these drawbacks Prof. Bridge's contribution to this volume is a valuable one. He has brought together a vast amount of information, much of which is the result of his own researches. Where he has had to draw upon the work of others he has for the most part selected of the best. Our chief complaint is that he is so meticulously exact.

The Teleostei, from a systematic point of view, are described by Mr. E. A. Boulenger, and he has brought to bear upon this most difficult task an unrivalled knowledge, tempered with rare skill and judgment. The classification which has been generally in use in this country for the last thirty years is now replaced by one which aims at being phylogenetic—the true basis of all systematic work. Although we believe Mr. Boulenger has improved on this arrangement in some minor details since passing the final proofs of his work some three years ago, it may be accepted as practically representing his views on this subject.

As he remarks, "Out of some 12,000 well-established species of fishes known to exist at the present day, about 11,500 belong to this order (Teleostei). The classification of such an array of forms is, of course, a matter of great difficulty, and gives scope for much difference of opinion among those who have attempted to grapple with the subject." The basis of this classification differs from that usually employed in other groups of vertebrates, inasmuch as it rests on osteological characters, in so far as families and higher groups are concerned.

The reader of this notice may imagine, from our ominous reference to dry bones, that Mr. Boulenger's contribution is of the nature of a dull and tiresome catalogue. We hasten to remark, therefore, that this element is effectually masked by the introduction of all the more important facts concerning the life-histories of the various species which have come within the author's province. These facts form most fascinating reading, and will appeal to a large number of people other than professed students of zoology. Do fishes sleep? is a question often asked. Although answered in the affirmative some eight and thirty years ago by Mobius, the fact has remained ever since practically buried in the German publication in which it appeared. Mr. Boulenger is apparently the first to give it circulation in a text-book. A species of Wrasse

confined in an aquarium, he points out, was observed by Mobius to seek a sleeping place at night, and to lay itself down to rest on one side. The psychologist and the student of evolution will find in these chapters of Mr. Boulenger a perfect mine of information. No more instructive lessons in adaptation can be gathered than from the descriptions and figures illustrating this part and certain sections of Prof. Bridge's work—as witness the text cuts given herewith.

ABORIGINAL INDIA.[1]

MR. BRADLEY-BIRT'S book dealing with the Santal Parganas merits the success achieved by his former volume on Chota Nagpore. This time, he lays his scene in the mountainous, forest-clad outlier of the Vindhyan range, which stands like an island in the midst of the great Gangetic plain. Dominating the great waterway which leads from the borders of the Punjab to the Bay of Bengal, it has for centuries been the stronghold of the aboriginal tribe who sought refuge in it from the Aryan flood descending from the north-west on the fertile plains of Bengal. From his almost inaccessible stronghold, the Paharia looked down upon the coming and going of the Hindu, the Pathan, and the Moghul. Empires rose and fell before his very eyes whilst he, hating the foreigner of every race and creed, remained wrapped in his primitive barbarism, a hunter living on the produce of the surrounding forest, not to be starved into submission, because he had no need of the produce of the plains. His only dealings with successive invaders were when he swooped on the villages below, killing and robbing their inhabitants, or cutting off travellers and the camp followers of passing armies. Neither Hindu nor Mahomedan could subdue him by main force without extravagant loss.

Attempts to bribe the mountaineer with land around the mountain failed, for he did not care to cultivate, and the keeping of a bargain with the hated foreigner formed no part of his moral code.

At last appeared the British, whose fair complexion impressed the Paharia with an idea that they were of higher origin than the earlier conquerors. In Augustus Cleveland came a man who found a way to tame the savage, to enlist his sympathy, and to offer an outlet for his martial instincts. Some of the Paharias were enlisted as an irregular force, whilst an endeavour was made to isolate the rest in a ring of neutral territory, from which the Hindu and the Mahomedan of the plains were to be excluded. Much of Cleveland's good work was undone by a successor of sterner and less considerate temperament. The solution of the difficulty was finally found, about 1830, when a wandering branch of the Santals, another aboriginal tribe, appeared upon the scene and eagerly accepted the land below the hills which the Paharia, refusing for himself, made untenable for the plainsman. The Santal, an enthusiastic though uncivilised cultivator, recognised as a kinsman by the Paharia, formed an efficient buffer between the hillman and the inhabitants of the surrounding plain. The Santal, in turn, gave trouble in 1856, when he broke into rebellion directed against the peaceful penetration of the moneylender and the landgrabber.

It is with these two aboriginal tribes that Mr. Bradley-Birt chiefly deals. As men, they are perhaps more interesting to the ethnologist and the philologist than to the ordinary student of human nature, but the author has succeeded in enlisting such interest as we can spare to one tribe still in the purely agricultural stage, and to another which has scarcely as yet progressed beyond that of the hunter.

His picture of village life on, and at the foot of, the Rajmahal hills glows with local colour and swims in the atmosphere of the jungle and the plain. It was scarcely necessary for him to assure his reader that most of the book was written in camp, in the midst of the Paharias and the Santals. As one reads, one seems to inhale the fresh, crisp air of an Indian cold weather morning, or to pant in the heavy atmosphere of the forest as the line of Paharia hunters presses, shouting and slaying through the dense undergrowth.

FIG. 1.—A Primitive Mode of Irrigation. From Bradley-Birt's "Story of an Indian Upland."

Much that Mr. Bradley-Birt describes, or depicts in his photographs, is not peculiar to the Santal Parganas. The primitive mode of irrigation, with basket swung by two men, which forms the subject of the illustration here reproduced, is still practised by millions who have never heard of the Santals, or been within a thousand miles of their home. All over India the cultivator watches his crops at night from a rough platform raised on a ricketty scaffolding of bamboos. Sometimes it happens, in regions not unlike the Rajmahal hills, that the vigil ends in a tragedy, when the sleepy watcher is torn from his post by the man-eating leopard. But the inclusion of these incidents in no way detracts from the charm of the picture of simple village life, a life of agricultural labour tempered by feasting and dancing in seasons when there is no labour to be performed.

The Paharias' rude religion has drawn nothing from Hinduism or Islam. The Santal equally professes his separation from those creeds, but his love of pleasure has induced him to adopt some of the Hindu festivals, for instance the Jatra, which he celebrates in February.

[1] "The Story of an Indian Upland." By F. B. Bradley-Birt. Pp. xvi+354. (London: Smith, Elder and Co., 1905.) Price 12s. 6d. net.

The history of British administration in this wild tract, up to the time of the Santal rebellion of 1856, can scarcely be held up as a great example. As for the patriarchal system which still prevails, Mr. Risley, in an introduction which, from the pen of so great an ethnological authority, is somewhat disappointing, throws some doubts on its superiority to other methods of dealing with aboriginal tribes. Perhaps, in later years, Mr. Bradley-Birt's enthusiastic admiration of it may cool. As matters stand, his enthusiasm, and his evident sympathy with the simple peoples he describes, serve to enhance the charm of his work.

To the Anglo-Indian this volume will recall much that is pleasant; to the tourist, and even to the stay-at-home Englishman, it will afford a bright glimpse of native country life which is not to be found on the beaten track.

NOTES.

At the meeting of the Royal Society on May 18 the following were elected foreign members:—Prof. L. Hermann, Koenigsberg; Prof. H. A. Lorentz, Leyden; Prof. H. Moissan, Paris; and Prof. Hugo de Vries, Amsterdam.

The annual visitation of the Royal Observatory, Greenwich, will take place on Saturday next, June 3.

The international conference having for its object the establishment of an international institute of agriculture was opened in Rome on Sunday, May 28, in the presence of the King of Italy. On Monday the conference held a sitting at the Accademia dei Lincei, and the Foreign Minister, Signor Tittoni, opened the proceedings with an address.

The English Arboricultural Society has been granted permission by the King to change its name to the "Royal English Arboricultural Society."

Prof. J. N. Langley, F.R.S., will give one of the general lectures at the meeting of the Association of German Naturalists and Physicians, which will open at Meran on September 24. His subject will be "Recent Researches on the Nervous System."

A Reuter telegram from Portici states that Vesuvius has for some days been in active eruption. At 7 p.m. on May 27 the western side of the small terminal cone collapsed, and a large quantity of lava burst forth, which in an hour's time reached the base of the great cone, at Atrio Cavallo, one kilometer distant.

We learn from the *Board of Trade Journal* that the *Gaceta de Madrid* for May 11 contained the text of a Royal Order providing for the duty-free admission into Spain of instruments and accessories carried by foreign men of science deputed to observe the eclipse of the sun on August 30.

According to a Reuter telegram, dated New York, May 27, the Cunard liner *Campania* reports that she was in continuous communication with land, by wireless telegraphy, throughout her entire voyage from Liverpool. In mid-ocean she had simultaneous communication with America and Europe, a feat which had not previously been accomplished.

A correspondent of the *Times* states that in the early part of May enormous shoals of dead fish were thrown up for a considerable distance along the sea coast by Karachi The whole beach was strewn with dead fish, lying in some places five or six inches deep. The Port Trust authorities had to make arrangements for the removal and burial of these millions of fish. Captain Belton, of the steamship *City of Dundee*, on arriving at Karachi reported some very curious electrical phenomena about a hundred miles out to sea, repeated flashes of light being observed to pass over the surface of the ocean in a curious way.

An international congress for the study of radiology and ionisation will be held at Liège on September 12–14 inclusive. The congress will be divided into a physical section and a biological section. The former will be concerned with the physics of electrons, radio-activity and dependent transformations, meteorological and astronomical phenomena and their relation to ionisation and radio-activity. In the biological section the subjects to be considered will include the physiological properties of various radiations and of radio-activity, and their medical value and application. The method of procedure in this section will be determined upon by a special committee presided over by Profs. Bouchard and d'Arsonval. The other members of this committee are Drs. Béclère, Bergonié, Broca, Charpentier, Charrin, Danysz, and Oudin. There will also be a general committee, presided over by M. Henri Becquerel, to examine, classify, and decide upon such reports, papers, and notes as may be offered. The acting president of the congress is to be Prof. H. Kuborn, president of the Royal Medical Society of Belgium, and the general secretary, to whom all communications or contributions should be sent as soon as possible, is Dr. J. Daniel, rue de la Prévoté, 1, Brussels.

Mention has already been made of the recent visit of British physicians and surgeons to Paris, and the cordial and enthusiastic welcome extended to them by French men of science, as well as by the State and municipal authorities. Further particulars of the visit are given in the *British Medical Journal* of May 20. Among the numerous receptions arranged by the scientific and medical societies and by civil bodies of every kind to do honour and give pleasure to the British visitors, no meeting was more appreciated than that which gave the British men of science the opportunity of paying homage to the memory of Pasteur. On May 11 the visitors attended at the Pasteur Institute to witness the ceremony of placing a wreath upon the tomb of Pasteur in the crypt of the institute by Dr. J. Kingston Fowler, dean of the medical faculty of the University of London. Dr. Roux, the director of the Institute, conducted the visitors and a distinguished party of French medical men to the gates of the crypt, where Dr. Fowler delivered in French the speech referred to in Nature of May 18 (p. 63), in which he craved permission to place a wreath on the tomb of the master, who accomplished so much for science and for humanity, and to whose labours the institute is a fitting memorial. Dr. A. Waller, dean of the faculty of science of the University of London, followed with an eloquent eulogy, also delivered in French. He laid great stress upon the value to humanity of Pasteur's work in the direction of the infinitely little, and spoke of Pasteur as *le médicin de la médecine*. Dr. Waller maintained that in a thousand years' time historians will not speak much of the nineteenth century as remarkable for the invention of the locomotive and other mechanisms, but rather as the epoch in which Pasteur inaugurated so brilliantly the study of the infinitely small. The earnest speeches, and the impressive scene as the visitors passed before Pasteur's tomb in respectful homage to their master, made the occasion a memorable one. The evidence thus given of the reverence in which Pasteur's memory is held should help to cement the friendly relations existing between France and Britain, and to foster that spirit of mutual confidence—that comity of nations—which already exists in the world of science.

THE May number of *Museum News* (Brooklyn Institute) contains an interesting notice of specimens in the collection illustrating the now obsolete manufacture of tapa cloth in Hawaii and other Polynesian islands.

A PRELIMINARY report, by Dr. H. W. Conn, on the fresh-water protozoans of Connecticut, issued as Bulletin No. 2 of the Connecticut Geological and Natural History Survey, is illustrated by no less than thirty-four beautifully executed plates. Hitherto the American fresh-water representatives of these lowly organisms have been but little studied, and the present research is merely a prelude to a fuller account of their distribution and their relation to the purity of drinking water. Descriptions of species are altogether omitted in this report, and even the generic position of some of the forms mentioned is left more or less undecided.

IN connection with the preceding paragraph may be appropriately noticed Mr. D. J. Scourfield's address (delivered in December last) on fresh-water biological stations, which is published in the April issue of the *Journal of the Quekett Microscopical Club,* since this also deals with the effects of organisms on the purity of water used for domestic purposes. The gradual awakening of interest in the subject of the detailed study of fresh waters and their organisms is sketched, and the history of the establishment of stations for the purpose briefly described, special reference being made to the one founded by Mr. E. Gurney on Sutton Broad, Norfolk, in 1902. The lecturer concludes with remarks about what fresh-water biological stations should be, whenever the requisite financial means are obtainable.

AMONG other monographs on American invertebrates recently received is a revision of the beetles of the family Staphylinidæ included in the section Pæderini. In this article, forming No. 2 of vol. xv. of the *Transactions of the St. Louis Academy,* the author, Mr. T. L. Casey, points out that the taxonomic problem presented by these beetles is one of great interest in reference to the comparative morphology of the tribe. Genera from all parts of the world are included in the revision, but with the exception of the types of new generic forms, the only species catalogued are those inhabiting America to the northward of Mexico.

IN an article on the affinities of Equisetum in the May number of the *American Naturalist* Prof. D. H. Campbell comes to the conclusion that these archaic plants are related to ferns rather than to lycopods, and that both ferns and equisetums are probably divergent branches from a common ancestral stock. In the same issue Mr. D. D. Jackson discusses the movements of diatoms, many of which appear to be due to the evolution of oxygen gas produced by the activity of the chlorophyll in these organisms. Attention may likewise be directed to Mr. A. H. Clark's paper on the habits of the important West Indian food-fish known locally as "whitebait" or "tri-tri" (*Sicydium plumieri*).

IN the report of the delegates of the University Museum for 1904, published on May 16 as a supplement to the *Oxford University Gazette,* special attention is directed by the Hope professor of zoology (Prof. Poulton) to the increase in the insect collection and the work that has been accomplished, or is in progress, in connection with the insect collection, which is rapidly becoming one of the finest in the world. The most recent addition is the collection of 7000 British Microlepidoptera presented by Mrs. Bazett, of Reading, another splendid acquisition being the collection of Hymenoptera and Lepidoptera bequeathed by Mr. G. A. J. Rothney. The report also alludes to the recent decisive confirmation of the existence of three distinct mimetic types of female in a South African Papilio, and to the remarkable features presented by certain southern butterfly faunas, which are almost wholly of a northern type. The editing of the Burchell manuscript, and the identification of the specimens in the collection of the great traveller referred to therein, are also mentioned.

AMONG the more important articles in the issues of the *Proceedings of the Philadelphia Academy* for the current year, the following may be specially mentioned. To the January issue Mr. C. W. Johnson contributes an annotated list of the type-specimens of Cretaceous invertebrates in the collection of the academy, while Mr. H. W. Fowler gives the second instalment of a paper on new or little-known scombroid fishes. Later on Mr. H. Crawley discusses the movements of gregarines; and in the February issue Mr. H. A. Pilsbry describes a number of new Japanese marine molluscs. Both entomologists and morphologists will find much to interest them in an article by Dr. E. F. Phillips on the structure and development of the compound eye of the bee, while Mr. Crawley's preliminary notice of a new sporozoon (*Coelosporidium blattellae*) found in the croton-bug (*Blattella germanica*), and Mr. T. H. Montgomery's contribution to our knowledge of the spermatogenesis of certain spiders and remarks on chromosome reduction, will appeal to specialists in such matters.

A RECENT issue of the *Jenaische Zeitschrift* contains the report of an address delivered in June last before the Medical and Scientific Society of Jena by Prof. E. Haeckel on the progress of biology in that city during the nineteenth century. Confining himself chiefly to morphology, and dwelling specially on the various theories which have been advanced in regard to that of the vertebrate skull, the professor pointed out that in Jena the "science century" may be divided into three periods. The first of these, during which Schleiden advanced the cell-theory, extended to 1838; then followed an interval of twenty years, after which, in 1859, came Darwin's epoch-making theory of the evolution of species. After referring to the work of Blatt on embryology and development, the lecturer emphasised the morphological importance of the "vertebral theory of the skull" enunciated by Goethe and Oken in the first third of the century, and of Huschke's labours in connection with the development of the skull and the sense organs in the second third. A whole paragraph is devoted to Goethe's discovery of the premaxilla in man. Oscar Schmidt, Johannes Müller, Carl Gegenbaur, and the other great names associated for longer or shorter periods with Jena and its teaching, receive in turn their share of praise in this admirable historical address.

MM. CALMETTE AND BRETON have repeated the experiments of Loos and others on the transference of infection in ankylostomiasis through the skin. They find that the larvæ of both the human and the canine Ankylostoma pass with the greatest facility through the skin of the dog, causing infection of the animal (*Acad. de Méd.,* Paris March 24).

THE *Bulletin of the College of Agriculture of the Imperial University, Tokyo* (vol. vi., No. 4), contains several papers of interest on the value and use of artificial manures for various crops, and others on the flowering of the bamboo, on oxidases, on the determination of fusel oil, on a bacillus observed in flacherie, &c. With regard to flacherie (a destructive disease affecting silkworms), the conclusion is

arrived at that it is not caused by any special bacterium, but by several different species of common occurrence on mulberry leaves.

We have received part ii. of the reports of the commission appointed for the investigation of Mediterranean fever, part i. of which has already been noticed in NATURE (May 4, p. 17). Dr. R. W. Johnstone deals with the sanitary circumstances and prevalence of the disease in the Maltese Islands, but is unable to give any definite pronouncement on the mode of human infection. The facts do not indicate that dust, personal contact, or excretal pollution play an important part in the spread of the disease. Staff-Surgeon Bassett-Smith, R.N., details experiments on the saprophytic life of the *Micrococcus melitensis,* and Dr. Eyre on the virulence of this organism for the guinea-pig.

The Bulletins of the Bureau of Government Laboratories, Manila, several of which have from time to time been noticed in these columns, always contain matter of interest. No. 20, in five articles, discusses various diseases occurring in the Philippine Islands, and in No. 21 Dr. Strong deals with certain questions relating to the virulence of micro-organisms and their immunising powers. The conclusion is arrived at that a virulent cholera spirillum possesses a greater number of bacteriolytic and agglutinable haptophore groups, or these groups are endowed with a greater binding power for uniceptors and amboceptors than the avirulent. That is to say, virulent cholera microbes have a greater capacity than avirulent microbes for uniting with living cells and their products.

An article on roses by Mr. Jekyll in the April number of the *Bulletin of the Department of Agriculture, Jamaica,* warns growers against attempting to grow hybrid perpetuals in the island. First place is assigned to the tea and noisette sections, which produce good results except in so far as the sun is too strong for some, and a good selection of suitable roses may be made from the list which is given.

A FLORA of the islands of Margarita and Coche, lying off the coast of Venezuela, is being prepared by Mr. J. R. Johnston, but meantime he has published a list of new plants from these islands in the *Proceedings of the American Academy of Arts and Sciences* (April). A new genus, Anguriopsis, is formed having affinities with the cucurbitaceous genus Anguria. Among the new species are a Bactris—a palm with handsome foliage—two new orchids, and several trees, including a Capparis, a Cæsalpinia, and a Casearia. The new species are for the most part additions to genera or sections of the genera which are confined to tropical America.

One of the most fruitful lines of recent research in botany has been concerned with the investigation of fossil seeds, of which several species of Lagenostoma are the best known. The evidence in favour of referring these seeds to certain vegetative portions of Carboniferous plants, formerly regarded as fern fronds, formed the subject of Dr. Scott's presidential address to the Royal Microscopical Society, which is published in the April number of the Journal. The cycadofilicinean position assigned to *Lyginodendron Oldhamium,* which shows a sphenopteris type of foliage, was confirmed by the evidence which connected the same plant with *Lagenostoma Lomaxi.* Mr. Kidston's discovery of the fructification of *Neuropteris heterophylla* fixed the seed to another typical fern-frond, and recent research points to the production of winged seeds by a species of Adiantites.

In a sketch of the geology of Upper Assam (*Records Geol. Surv. India,* xxxi., part iv.) Mr. J. Malcolm Maclaren describes the region as a great plain, 320 feet to 500 feet above sea-level, bounded on the north-west by the eastern Himalayas and on the south-east by the Patkai ranges, while the head of the valley is closed in by the crystalline and metamorphic rocks of the Miju ranges. Upper Tertiary sandstones occur at a considerable height (maximum 6900 feet) on the Patkai and Himalaya ranges, but have not been observed anywhere on the heights of Miju. Attention is directed to the general uptilting and reversed faulting of the Tertiary rocks on either side of the great plain, and to the deflection in the trend of the Patkai range where it abuts against that of Miju. These features are attributed to earth stresses during the formation of the mountains. The author concludes that the Patkais and Himalayas, in their later growth at least, are of contemporaneous development, and that both are orographically and geologically distinct from the great meridional mountain system of Upper Burma, Tibet, and western China. In another article Mr. Maclaren deals with the auriferous occurrences of Assam. Gold was there worked in ancient times, and it is distributed in extremely small percentages throughout the alluvial gravels of the Brahmaputra; but the author is of opinion that only two or three localities are worthy of further prospecting, and that these are likely to yield comparatively small results. He believes that in Assam, as in most other parts of India, the climatic conditions that make for concentration of gold have always been absent. There never has been that even flow of waters confined within well-marked banks, that after a lengthened period results in a separation and local concentration according to specific gravity of the river-borne minerals in "leads" and "runs." On the other hand, there have been annual floods, varying so quickly in height, velocity, and direction that the slight local concentration of one year has been effaced by succeeding floods.

We have received vol. ii. of the year-book of the Austro-Hungarian Meteorological Observatory of Agram for the year 1902, a large folio publication containing fifty pages of tables giving detailed and summarised observations and results at a number of stations in Croatia and Slavonia. The size of the work is somewhat unwieldy, but the tables are very legible, and have been carefully prepared on the plan of the international scheme for meteorological publications. Hourly readings, and hourly and daily means, are given for Agram.

The recently published annual *Journal of the Scottish Meteorological Society* (third series, Nos. 20 and 21) contains an interesting discussion of the rainfall of the Ben Nevis observatories, by Mr. Andrew Watt. The measurement of precipitation on the summit was attended with great difficulties; the high wind velocities, at an altitude of 4400 feet, made the registration of snow (which mostly falls between October and May) and even of rain somewhat uncertain. The tables show the falls at the upper and lower stations for the nineteen-year period 1885–1903. The average annual rainfall at the summit was 160·8 inches, and that at the foot 78·6 inches; in individual years the amounts varied from 49 per cent. above to 33 per cent. below the mean values on the summit, and from 45 per cent. above to 23 per cent. below at the lower station.

With regard to daily range, the author states that, speaking very generally, rain falls more frequently, but less heavily, by night than by day, at the foot of the mountain; whilst on the summit the variations are less pronounced, but, on the whole, are in sympathy with those at Fort William. On the top of the mountain falls of 4 to 6 inches in a day were occasionally recorded.

A GOOD oil-immersion lens at a moderate price has long need has been met by Mr. Gowlland, of Selsea, who has been wanted by histologists and bacteriologists. This produced an objective of 1/12-inch focal length and 1·30 numerical aperture at a price of 2*l*. 15*s*. It is an admirable piece of apparatus, and is well corrected for spherical and chromatic aberration. We have tested it on a number of objects, and can recommend it as thoroughly efficient. It is claimed by the maker that it has good photographic qualities.

IN a paper published in the *Gazzetta* for April 3, Dr. Italo Bellucci proves that the so-called hydrated platinum oxide, $PtO_2,4H_2O$, is in reality a platinic acid of the structure $H_2Pt(OH)_6$, corresponding with chloroplatinic acid H_2PtCl_6, and forming a series of well defined salts of the type $M_2Pt(OH)_6$. In a second paper, written in conjunction with N. Parravano, the metallic stannates and plumbates are shown to be derived from similar acids, $H_2Sn(OH)_6$ and $H_2Pb(OH)_6$, whilst the three salts $K_2Pt(OH)_6$, $K_2Sn(OH)_6$, and $K_2Pb(OH)_6$ are strictly isomorphous. The views brought forward are of considerable importance from the standpoint of the systematisation of inorganic chemistry, and as showing that so-called water of crystallisation may in many instances play an important part in molecular structure.

SINCE Lord Rayleigh published in 1897 his interesting results on the oxidation of atmospheric nitrogen by an electric arc, many attempts have been made to devise a practical method of synthesising nitric acid from the gases of the atmosphere. Owing, however, to the fact that nitric oxide is formed by an endothermic change and to the early production of a condition of equilibrium when little oxidation has occurred, the processes hitherto published have been far from economical. In the *Gazzetta* for April 3 E. Rossi describes how the efficiency of such methods may be greatly increased by working with air under a very great pressure. The heating is effected by means of an incandescent resistance similar to the filament of a Nernst lamp, and the nitric oxide is absorbed by concentrated sulphuric acid within the interaction chamber, as fast as it is produced, so as to obviate an equilibrium.

IN the *Verhandlungen* of the German Physical Society (vol. vii. p. 78) L. Graetz replies to the objections raised by Profs. Precht and Otsuki (compare NATURE, vol. lxxi. p. 468) against his view that hydrogen peroxide gives rise to a special radiation capable of affecting a photographic plate. He considers that a substance so comparatively non-volatile as hydrogen peroxide, which has a vapour tension less than that of water, and can be concentrated by allowing a current of air to pass through it, cannot be conceived as directly permeating sheets of celluloid and gelatin. Again, the extreme readiness with which hydrogen peroxide is decomposed catalytically by metals makes it improbable that it would pass as such through minute holes in thin metallic plates. In a second communication, published in the same periodical (vol. vii. p. 163), Profs. Precht and Otsuki maintain their original contention by emphasising the minuteness of the quantity of hydrogen peroxide necessary to affect a photographic plate. The action of the peroxide on sensitive plates has since been discussed in detail by Prof. Otsuki in a paper read before the Society of Chemical Industry on May 1.

A HERBERT SPENCER lectureship has been founded at Oxford by a Hindoo gentleman who is a Master of Arts of Balliol College. The first lecture was delivered on March 9 by Mr. Frederic Harrison, and has been published by the Clarendon Press. It is appreciative, but not—lecturer or printer has surely blundered in regard to the prefix—"an apodictic eulogy." Mr. Harrison's chief criticisms of the synthetic philosophy are:—(1) that, laying all the emphasis on evolution, it disregards the laws of stability and permanence, such as are manifested chiefly in the inorganic sciences—which it accordingly passes over; (2) that its attempt to reduce all manner of sciences under the same laws only succeeds because it neglects the peculiarities which make any one science or set of sciences incommensurable with others, as, *e.g.*, the human sciences are with the non-human. But the lecturer readily admits that Spencer did not allow himself to be confined by the materialistic dogmas with which he set forth, and that while "Philosophy never opened with aspect more physical, it never insisted more imperatively on the law of Justice from man to man, on the supreme duty of Altruism."

THE thirty-fifth of the privately printed opuscula issued to the members of the Sette of Odd Volumes is entitled "The Early History of the Royal Society." The author of this brochure is Mr. Henry B. Wheatley, sometime clerk to the Royal Society, who has succeeded in writing a very interesting account of the early years of our national association of men of science. Mr. Wheatley shows that Charles II.—"Founder, Patron, and one of the Royal Society of London for improving Natural Knowledge"—took a genuine interest in the advancement of the society. "True he did not give any money, but then money was never very plentiful with His Majesty. He was always ready to assist with his name and influence. His interest doubtless made the Society the fashion." Doubt is cast on the truth of the story of the paradox put forward by Charles II. concerning the weights of respective bowls of water with or without fish in them. A suggestion of Sir William Petty, the inventor of the double-bottomed boat, as to the society's anniversary, is worth repetition. Aubrey writes:—"I remember one St. Andrew's day I sayd methought it was not so well that we should pitch upon the Patron of Scotland's day. We should rather have taken S. George or S. Isidore, a philosopher canonized. No, said Sir William Petty, I would rather have had it been S. Thomas's day." Objections were on one occasion made to Charles II. that a member recommended by him for election was a shopkeeper. By way of reply the King "gave this particular charge to his Society, that if they found any more such tradesmen they would be sure to admit them all, without any more ado." Mr. Wheatley records many more quaint stories and odd incidents associated with the society's earlier years, and his paper will excite lively interest in all scientific readers who are able to obtain a copy of it.

MR. HENRY FROWDE has published in pamphlet form the Robert Boyle lecture delivered by Prof. H. B. Dixon, F.R.S., before the Oxford University Junior Scientific Club in 1903, on the nature of explosions in gases.

NEW editions of "Half Hours with the Microscope," by Dr. Edwin Lankester, and "The Preparation and Mounting of Microscopic Objects," by Mr. Thomas Davies, have

been published by Messrs. C. Arthur Pearson, Ltd. Dr. Lankester has made important additions to his book descriptive of the compound microscope and its accessories, and has incorporated a chapter by Mr. F. Kitton on the polariscope and its uses. Dr. John Matthews has edited the second book, and has made several alterations and additions, among the latter being a prefatory chapter dealing with preliminary histological manipulation.

THE *Bulletin de la Société des Naturalistes de Moscou* (1904, Nos. 2 and 3) contains the following papers:—Four notes on the crystalline forms and optical properties of various salts.—On the theory of endosaprophytism with lichens, by A. Elenkin. A defence of the latter as against the mutualistic theory, with a bibliography of the literature of the subject (in German).—The Jurassic corals of the Sudagh, by A. Missuna (with plates). In a total of 108 species, 46 are new for the Crimea, and 14 new species are described. The Crimean coral-fauna has its nearest relative in the Jurassic fauna of Switzerland (this paper is in German).—Materials for the algology of Lake Baikal, by V. Dorogostaïsky (with a plate). Results of a two years' study of the algæ in Lake Baikal and its affluents. A list of 350 species is given, a few of them being new (this paper is in French).—History of development of the excre tory system with the Amphibiæ, D. P. Filatow (in German, with a plate).—The same number contains a fine portrait of Prof. T. A. Bredikhin, and a biographical sketch of the late Moscow astronomer, including a sketch of his theory of comet tails, by P. K. Sternberg.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JUNE:—

June	2.	Venus at maximum brilliancy.
,,	11.	13h. 3m. Minimum of Algol (β Persei).
,,	12.	8h. 22m. to 9h. 24m. Moon occults l^2 Virginis (mag. 4·9).
,,	13.	Saturn. Outer major axis of outer ring=40″·87; outer minor axis of outer ring=6″·03.
,,	,,	9h. Mars in conjunction with moon, Mars 6° 14′ S.
,,	14.	9h. 52m. Minimum of Algol (β Persei).
,,	15.	Venus. Illuminated portion of disc=0·365; of Mars =0·938.
,,	21.	15h. Sun enters Cancer, Summer commences.
,,	,,	22h. Saturn in conjunction with Moon, Saturn 1° 29′ S.
,,	23.	23h. Uranus in opposition to the Sun.
,,	27.	14h. 48m. to 16h. 33m. Transit of Jupiter's Satellite III. (Ganymede).
,,	29.	14h. 10m. to 15h. 1m. Moon occults θ^2 Tauri (mag. 3·6).
,,	,,	14h 15m. to 14h. 56m. Moon occults θ^1 Tauri (mag. 3·9).

A REMARKABLE VARIABLE STAR.—In a note published in No. 4017 of the *Astronomische Nachrichten* Prof. E. C. Pickering states that the light-changes of the variable star 154428, R Coronæ Borealis, are unlike those of any other known variable. A series of observations, made by Mr. Leon Campbell, showed that during the period March-September, 1903, the magnitude underwent remarkable changes between the limits 6·0 and 9·4. Since then until March of the present year it remained stationary at 6·0 m. The unusual character of the changes during April and May is shown in the following table:—

1905	Mag.	1905	Mag.
April 1	6·0	May 1	11·4
11	7·3	7	12·5
21	8·4		

Observations with large telescopes are now desirable in order to see whether or not this object disappears entirely. It is easily recognised on the Harvard "Map of the Sky," plate No. 18 (118·75), and is nearly equidistant from γ, δ, and ϵ Coronæ.

RADIAL VELOCITIES OF THIRTY-ONE STARS.—For the past ten years line-of-sight observations have been made at the Emerson McMillin Observatory (Columbus, Ohio), but Prof. Lord has now arrived at the conclusion that, as so many better equipped observatories, situated in more favourable atmospheres, are engaged in this work, it seems advisable to discontinue the observations there and direct the available resources into some other channel of research for which they are better equipped. Consequently he has collected all the results obtained during the decennary, and has published them in No. 4, vol. xxi., of the *Astrophysical Journal*. Complete catalogues of the plates taken and of the standard lines employed, and the collected results, are embodied in his communication. Amongst the thirty-one stars dealt with there occur α_1 Cassiopeiæ, Aldebaran, α Arietis, α Persei, Capella, Pollux, Dubhe, Arcturus, β and γ Cygni, and δ Cephei.

MAGNITUDES OF NOVA PERSEI AND NOVA GEMINORUM.—In No. 4017 of the *Astronomische Nachrichten* Prof. A. A. Nijland publishes the results of a number of magnitude observations of Novæ Persei and Geminorum. The observations of the former covered the period November 15, 1901, to January 13, 1905, and the figures given show frequent increases of brightness, which were, however, very small. A gradual decrease of magnitude underlies these minor fluctuations, and on January 13 the Nova was of magnitude 10·74.

The Nova Geminorum observations extended over the period March 27, 1903, to December 30, 1904, and on the latter date the magnitude recorded was 13·3, more than 2·7 magnitudes fainter than Nova Persei on the same date.

OXFORD UNIVERSITY OBSERVATORY.—Prof. Turner's report of the work done at the Oxford University Observatory during the twelve months ended April 30 informs us that the Oxford work in connection with the International Astrographic Catalogue is at last within measurable distance of publication. The measures and reductions were completed last year, and the whole thing is now ready to print. What is still more satisfactory, the university has set aside 1000*l*. for this purpose, and this is to be supplemented by a similar contribution from H.M. Government.

The stereo-comparator has been used to compare some of the newer with some of the older plates, but, so far, nothing of importance has been discovered; more time will be given to this work when the coming eclipse is past and the Oxford contribution to the International Catalogue is safely in the press. As some of the earlier plates for the catalogue are less satisfactory than the later ones, they are being duplicated, and the new ones are being measured and reduced as opportunity occurs. An expedition from the observatory, comprised of Prof. Turner and Mr. Bellamy, will observe the total solar eclipse of August next in Egypt.

VARIATIONS OF LATITUDE.—The provisional results of the work accomplished by the International Latitude Service during 1904 are given by Prof. T. Albrecht in No. 4017 of the *Astronomische Nachrichten*. The results obtained at the six stations employed in the service are grouped, and the variation of the momentary from the mean pole during the years 1900–4 is graphically shown. From this curve it appears that the year 1904 was marked by a diminution in the amplitude of the variation.

NEW REFRACTION TABLES.—Appendix ii., vol. iv. (second series), of the *Publications of the U.S. Observatory* contains a number of reduction tables for transit-circle observations compiled under the direction of Prof. Eichelberger. All of them, except the refraction tables, are of no use at any other observatory, but these may be found useful by other transit observers. They consist of nine separate tables, in which the logarithms of the various arguments necessary for determining the exact refraction correction for each minute of apparent zenith distance from 0° to 85° are given. An example which precedes the tables clearly illustrates the method of using them. The tables are based upon those of Pulkowa.

ISLANDS FOR WEATHER FORECASTING PURPOSES.

THE aim of meteorology from a practical point of view is the forecasting of the amount of rainfall and the approach of storms.

The former will tell us whether we may expect high river flows producing floods and much damage, an average amount of water for successful crop production, or a deficiency of rain which might result in a disastrous drought and possibly a famine. In the case of storms, a means will be afforded of saving many lives and ships, and also, probably, much property ashore.

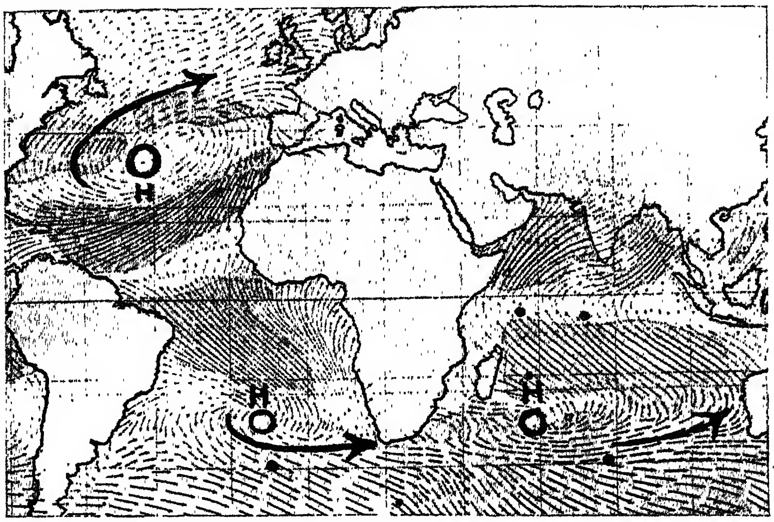

FIG. 1.—The wind system during summer in the northern hemisphere and winter in the southern hemisphere. The black dots represent islands, and the letter H the centres of regions of high pressure or anticyclonic areas.

The study of the weather, therefore, should be fostered to its fullest extent, and every advantage should be taken of means which will bring us nearer the goal of satisfactory forecasting.

Investigations carried out during the last decade have indicated the importance of each weather bureau extending its area of inquiry beyond the region for which it is making its forecasts. Needless to say, many of these institutions have for some years been in telegraphic communication with outlying stations. Thus, for instance, the Indian Meteorological Service receives information from a station so far distant as Mauritius, while the U.S. Weather Bureau utilises valuable observations by telegraph from stations in the West Indies, Azores, Europe, &c.

It is important to bear in mind that rain-bearing winds are those that have passed over large stretches of water, and that the rainfall of a country is deficient or well supplied with this commodity according to its geographical position in relation to the oceans or inland seas, mountain ranges, and the prevailing winds. It is for these reasons that the nearer the coast is approached from the centre of any continent, the greater becomes the rainfall. Thus, for instance, the interior of Australia, the Sahara, the Arabian Desert, Tibet, &c., are all very dry areas.

For forecasting purposes, therefore, attention should be, and in many regions is, paid to the region from which the prevailing winds come, due consideration being given to the particular barometric system of which the wind forms part.

From the above the important functions of islands conveniently situated become obvious. It is not, however, every country bordering on the ocean that is blessed with such an island in the direction of the prevailing wind, and the British Isles, in consequence, suffer very much from this very defect. In Great Britain the main rain-bearing wind is that from the south-west. In summer this forms part of a large anticyclonic system situated in mid-Atlantic towards the south-west (see Fig. 1), while in winter it is a portion of a cyclonic system the centre of which is near Greenland (see Fig. 2). With no islands in the track, the only meteorological information that is at once useful is that which can be gathered from messages sent by the Marconi system of wireless telegraphy from steamers *en voyage*. British weather forecasters are thus undoubtedly heavily handicapped by the lack of some permanent outlying source of information in this region.

Mention has already been made of the use of islands by the United States and India. The latter is particularly fortunate, for Mauritius, Seychelles, Chagos (marked with dots in the figures), and other islands are all conveniently situated to render information if necessary.

Another region which very probably would gain considerably by utilising observations made at island stations is South Africa.

In a previous number of this Journal (vol. lxxi. p. 342, February) Mr. E. Hutchins, Conservator of Forests, Cape Town, gave an excellent account of the general weather conditions in this region. He pointed out that South Africa lies on the border of the south-east trade area. In summer, from Cape Town to the Zambesi, the country comes entirely under the influence of the south-east trade winds. In winter, on the other hand, the southern portion of Cape Colony is subject to "another type of weather, due to the passage of storms from the South Atlantic, the

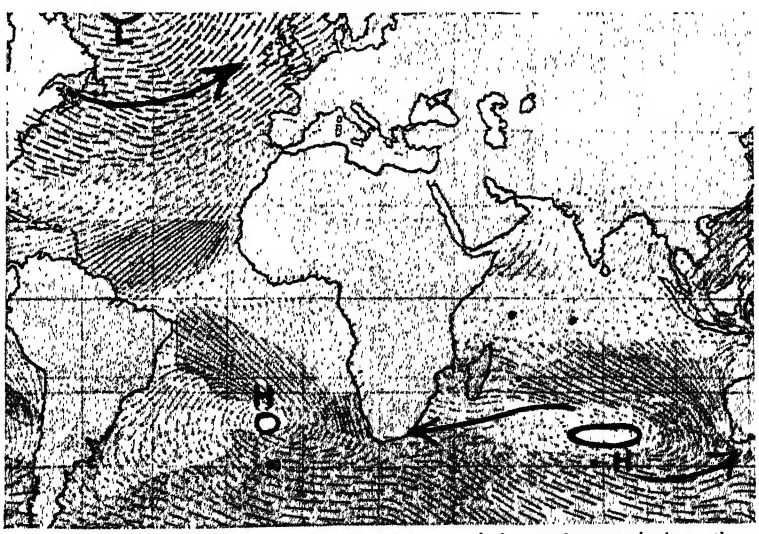

FIG. 2.—The wind system during winter in the northern hemisphere and summer in the southern hemisphere. Notation as in Fig. 1. The letter L indicates the centre of a low pressure or cyclonic area.

'roaring forties' of mariners." He further directs attention to the need of distinguishing between these two weather systems, which play distinct parts in the meteorology of this region. A study of the accompanying two figures will indicate the importance of the islands of Tristan d'Acunha and Gough (indicated by a black dot towards the south-west), and also of Mauritius (the dot east of Madagascar). The two former islands lie in the wind system pertaining to the anticyclonic (high-pressure) area on the west, the centre being indicated by the letter H, while Mauritius, situated to the east of South Africa, is in the south-east trade area in the system formed by the high-pressure (anticyclonic) region, the centre of which is marked also with an H.

By observing the general trend of the air currents indicated by the large arrow, it will be seen that for the winter season in South Africa (Fig. 1) meteorological observations made in either Tristan d'Acunha or Gough Islands would undoubtedly render valuable aid to the weather forecasters.

In the case of the summer months (Fig. 2) there is no conveniently placed island that could furnish equal assistance, but it seems very possible that use could be, and most probably has been, made of the observations at Mauritius for determining the strength of the south-east trade current which impinges on the African coast at this time of year. For forecasting purposes Mauritius, and possibly Rodrigues, would have greater value for regions further up the African coast.

Unfortunately, the Amsterdam and St. Paul islands (marked with one dot) lie too far south and east to serve as useful outlying stations for South Africa. On the other hand, these islands should be undoubtedly utilised by the Australians.

An examination of the accompanying figures indicates the relative positions of the Australian continent and this large southern Indian Ocean wind system. These islands will thus be seen to be right in the track of the current which strikes the south and west coasts of Australia, and should form ideal out-stations for gauging the general condition of this wind system.

That the prevailing winds on the west coast of Australia come from a southerly direction is indicated in the following table, which gives the number of times the wind has blown from each point of the compass at the Perth Observatory during the year 1902, the readings being taken eight times a day :—

N.	98
N.N.W.	51
N.W.	73
W.N.W.	67
W.	92
W.S.W.	113
S.W.	232
S.S.W.	432
S.	425
S.S.E.	245
S.E.	194
E.S.E.	121
E.	157
E.N.E.	139
N.E.	159
N.N.E.	98

Another table shows that the resultant direction of the wind, at the same observatory for the same year, was south for the months January to April and October to December inclusive.

There seems every reason, then, to hope that the utilisation of information from one of these islands for several months in the year would in time amply repay the initial cost and maintenance of the station.

It is not without interest to remark that the air current which passes the west coast of Australia in July (that is, in winter in Australia) becomes later the south-east trade wind of the Indian Ocean, and eventually reaches the Indian area in the form of the south-west monsoon in the summer months of the northern hemisphere. In the months about July, Western Australia is thus apparently closely connected, meteorologically speaking, with India, but in the months about January the connection is between Australia and South Africa.

The natural deduction to be made from the above is that the meteorological services of all these countries should be closely in touch with each other. Their combined efforts will certainly considerably increase our knowledge of the meteorology of this vast region, and each will benefit by this mutual interchange of information.

Although mention has only been made of one or two instances in which the employment of islands as meteorological stations would most probably be rewarded with practical results, there are other countries that might equally profit by adopting the same principle.

It is, however, important for the study of world meteorology that many islands should be employed as observing stations. They may not be very ideal places for observers to live in, but a change every few months, and the adoption of self-recording instruments, would possibly simplify matters. Where cables are lacking, and the island in question is of great meteorological importance to some continent, wireless telegraphy might be employed with advantage. WILLIAM J. S. LOCKYER.

AN OPTICAL CONGRESS AND EXHIBITION.

THE aims of the optical convention, which was opened at the Northampton Institute, Clerkenwell, on Tuesday, May 30, are to increase the interest taken in optical science in this country, to promote an improvement in technical education in optical matters, and to aid the development of the British optical industry. In his address, the chief part of which is subjoined, the president, Dr. R. T. Glazebrook, F.R.S., after explaining the origin of the proposal to hold a convention, and the steps taken to realise it, gives an outline of the history of optical progress during the past two hundred and fifty years with the view of illustrating the close union which has existed between theory and practice at times of marked progress, and of showing how each has reacted on the other in assisting this progress. The programme of the convention includes meetings for papers and discussions, which will be subsequently published in a volume, and an exhibition of optical and scientific instruments of British manufacture, with a catalogue which is intended to serve as a work of reference illustrating the productions of opticians in this country. A description of some of the exhibits follows the president's address abridged below; and an article on the nature and matter of the papers and discussions will appear in these pages after the close of the convention.

PROGRESS OF OPTICAL SCIENCE AND MANUFACTURES.[1]

The study of optics is a fascinating one, and its history full of interest. I do not propose to-night to attempt to cover the whole ground, but to ask you to look at one or two special periods during which, it seems to me, theory and practice reacted on each other in a marked manner, and to consider what lessons we may draw as to the relation which should in these days of ours subsist between the two.

For this purpose I might go back to very early days. Ptolemy in his attempt to discover the laws of refraction —and wonderfully good the attempt was, as we know now —Archimedes with his burning glass, if, indeed, he ever made it, had both practical aims in view. But we will start to-night nearer our own time. The end of the seventeenth century is such a period. The telescope was invented about 1608, the microscope at rather an earlier date, about 1590, both, probably, in Holland.

Galileo, hearing of this, made his first telescope in 1610. In 1611 Kepler, in his "Dioptrica," described the astronomical telescope with one or more convex lenses as the eye-piece; with this exception, up to Descartes's book on "Dioptrics" in 1637, no other form of telescope but Galileo's was known. The law of refraction was first enunciated by Snell in 1621.

Thus by the year 1660 the importance of the telescope to the astronomer was fully appreciated, and its limitations were being realised. In 1663 Gregory published an account

[1] From the inaugural address delivered before the Optical Convention on May 30 by the president, Dr. R. T. Glazebrook, F.R.S.

of the first reflecting telescope designed to meet some of these defects, and about this time two men, whose work has left indelible marks on the science, were led to study it in a great measure from their interest in astronomy—Christian Huyghens, who lived from 1629 to 1695, and Isaac Newton, 1642 to 1727.

Huyghens was the discoverer of the wave theory and of the law of double refraction, but he was also a skilled mechanic, and he worked himself at grinding his lenses and erecting his telescopes. He realised from a consideration of the theory that many of the most marked defects were due to the fact that the rays from a distant star traversing the various parts of the lens were not brought to a focus at the same point on the axis, and that for a lens of given aperture this axial aberration decreased rapidly as the focal length increased. The magnification of the telescope depends on the ratio of the focal length of the object glass to that of the eye-piece. Hence by keeping this ratio constant, and increasing both focal lengths in the same proportion, the magnification could be maintained and the spherical aberration decreased.

Thus he was led to make lenses of 120 feet focal length. Tubes for such instruments could not be produced, and they were mounted on the top of tall poles and moved from below by ropes. With one of these telescopes, which he afterwards presented to the Royal Society, he discovered Saturn's rings and its fourth satellite. In this case the desire to improve an instrument caused an appeal to theory, and theory led the optician to make a real advance. The advance, it is true, was an inconvenient one, and the defects, as we shall see, were not entirely due to spherical aberration, but the fact remains.

In another branch of instrument making Huyghens is famous for applying science to manufacture. His treatise "Horologium Oscillatorium," which discussed most ably many problems of motion, was long the standard work on clocks, and he was the first to bring into practical use, in 1657, the pendulum as a regulator for time measurements, though according to Sir E. Beckett the first pendulum clock actually made was constructed in 1621 by Harris, of London, for St. Paul's Church, Covent Garden.

In 1665 a posthumous work of an Italian Jesuit, Francis Maris Grimaldi, entitled "Physico Mathesis de Lumine, Coloribus et Iride aliisque annexis," was published at Bologna. It contains some notable observations, particularly the discovery of diffraction.

Newton, who in the previous year had taken his B.A. degree at Cambridge, purchased a prism at Stourbridge Fair in 1666 "to try therewith the celebrated phenomena of colours," and to repeat some of Grimaldi's experiments. During that year also he had applied himself to the grinding of "Optic Glasses of other figures than spherical." He was already interested in astronomy, possibly had already made, but not confirmed, his great discovery. Writing to Halley in 1686 about some of the controversies which followed the publication of the "Principia," he says:—"But for the duplicate proportion I gathered it from Kepler's theorem about twenty years ago."

The celebrated apple is supposed to have fallen in his mother's garden at Woolsthorpe, in Lincolnshire, in 1665, where he was driven by the plague, and the story has some authority. It is stated to be the fact by Conduitt, the husband of Newton's favourite niece; it was told by Mrs. Conduitt to Voltaire, and the tree from which it was said to have fallen was seen by Sir David Brewster in 1820.

Various suggestions have been made, for the reason why the discovery that the same cause which produced the apple's fall also maintained the moon in her orbit was not published for many years; the true one is probably due to Dr. Glaisher, who pointed out that it was necessary to know the attraction not merely between two particles of matter, but between two spherical bodies of large size, and that this problem was not solved until much later; but, be this as it may, we are sure that in 1667 Newton was an astronomer, and realised the necessity for accurate astronomical observations, and all that the improvement of the telescope meant to astronomers.

Now his experiments with the prism in 1666 led to the discovery of the spectrum; little was known about colours at that time, and Dr. Barrow's "Treatise on Optics," published with Newton's help in 1669, contains very erroneous views; but some time shortly after that date Newton was able to draw the important conclusion that white light is not homogeneous, but consists of rays some of which are more refrangible than others; the pictures of the spectrum, so familiar to us in numerous text-books, come from Newton's "Optics," published first in 1704, though his discoveries as to the analysis of white light were laid before the Royal Society in various papers in 1671, and were given in lectures on optics as Lucasian professor in Cambridge in 1669, 1670, and 1671.

The bearing of all these physical experiments and researches on the practical manufacture of the telescope was at once obvious; the lenses behave like prisms, and decompose the light into its constituent colours. No alteration of shape will remove this entirely, and Newton was driven, too hastily as we know now, to the conclusion that the refracting telescope could not be greatly improved; its defects were inherent in the refraction of light.

The defect, however, does not exist in images formed by reflection, and he came to the conclusion that optical instruments might be brought to any degree of perfection imaginable provided a reflecting surface could be found which would polish as freely as glass and reflect as much light as glass transmits, and provided a method of communicating to it a parabolic figure could be found. In 1668 he thought of a delicate method of polishing by which he believed "the figure would be corrected to the last," and the Newtonian reflecting telescope was the result. An instrument made with his own hands is now in the possession of the Royal Society, and the many noble instruments which have added so greatly to advance our knowledge of the stars are the direct outcome of Newton's experiments with the prism and the deductions he drew from them.

But these experiments convey another lesson, for Newton, misled by his observations on dispersion, decided, wrongly, as we know now, that achromatic lenses were impossible, and that the colour defects must always exist in reflecting instruments; and as a result attempts to improve these instruments were almost in abeyance for nearly ninety years. Two or three achromatic telescopes were made by Mr. Hall about 1730, but it was not until 1757 that Dollond re-invented this instrument and commenced the regular construction of such lenses.

Thus the discoveries of Huyghens and of Newton reacted powerfully on the instruments of their day. Indeed, in each of these two instances the discoverer and the instrument maker were the same person. Such a combination may be less possible now; still, there are mathematicians skilled in the theory of optics and opticians skilled in the practice of their art.

The Optical Convention aims at coordinating the efforts of the two. But if 200 years ago the progress of the telescope was determined by the advance of optical theory, theory itself was no less indebted to the interest in instruments and observations thus aroused for the progress that took place.

Huyghens was the founder of the wave theory, though the labours of Young and the genius of Fresnel were necessary before Newton's rival theory of emission was displaced.

For nearly 100 years after the date of Newton's "Optics" progress was slow. The world was occupied in assimilating what he had taught. English mathematicians, overawed, perhaps, by his transcendent greatness, employed themselves in expounding his teaching. In England, at any rate, the emission theory was supreme, and few, if any, questioned his dicta as to the impossibility of achromatism.

But a change came with the new century. Thomas Young, 1773–1829, was the first in his various papers between 1801 and 1811 again to direct attention to Huyghens's work, and to place on a firmer basis the ground-work of the wave theory. He it was who established clearly the principle of the superposition of waves, and showed how interference may be explained by it.

Young's work, however, would have been incomplete without Fresnel (1788–1827), who re-discovered for himself the principle of interference and extended it to explain diffraction, besides enunciating his theory of double re-

fraction and deducing the well known expressions for the intensity of the light reflected from or transmitted by a transparent surface.

Young, in his "Lectures on Natural Philosophy," illustrated in an admirable way the applications of optical theory to instruments. Fresnel was an engineer by profession attached to the service of the bridges and roads, and as such was the inventor of the arrangements of lenses employed in the French lighthouses.

The discoveries of these two men changed the whole of the theory on which the construction of optical instruments is based; it is idle to attempt to explain the action of a microscope, the resolution of a double star or of the fine lines of the spectrum, to discuss the conditions for such resolution, or, instead, to attempt the construction of any of the more delicate of the beautiful apparatus about us without clearly understanding the fundamental laws discovered by these two, and verified with marvellous skill by Fresnel in his country home in Normandy, not by the aid of modern apparatus, but by such means as his own hands, aided by the skill of the village blacksmith, could construct; and though it is true that only recently have we appreciated the full importance of the wave theory in its bearing on the construction of optical instruments, it is the fact that without their labours and the work of those who followed in their path few of the modern discoveries of the astronomer, few of the results which the skilled optician of to-day has arrived at, would have been possible. The object glass of a microscope, the lens of a camera or a telescope, have reached their present perfection because men have been found who could apply to the art of lens grinding the highest teaching of Young and of Fresnel.

In the earlier years of the last century Englishmen were well to the fore in this work. In astronomy the labours of the two Herschels are well known, and though, perhaps, the success of the elder Herschel was due rather to his mechanical skill than to a profound knowledge of optical theory, Sir John Herschel advanced in no small measure the application of theory to practice.

At a somewhat earlier date Fraunhofer, of Munich (1787–1826), a contemporary of Young and of Fresnel, had realised the fact that the development of the achromatic lens "depended on the exact determination of refractive indices, and that the chief difficulty in that determination lay in the difficulty of obtaining homogeneous radiations to serve as standards" (Schüster, "Theory of Optics").

For these he used the dark lines of the solar spectrum, originally observed by Wollaston, and in this we have an example of the manner in which practical needs react to assist in the advance of science, for from these observations springs the whole of spectrum analysis and all that is involved in that.

Thus theory and practice progress together; each alone carries us but a short way, but the judicious use of hypothesis and reason, supported by the verdict of experiment, carries us on to new knowledge, and brings us nearer to the truth.

Until after the middle of last century we in Britain took our full share in promoting this advance. We might add to the names already mentioned those of Sir George Airy and of the distinguished men who, in the first half of the century, adorned Trinity College, Dublin, notably Sir William Hamilton.

Sir George Airy gave, about 1802, an account of the aberration of the lens of the camera obscura of the utmost value to the early designers of the photographic lens, while Sir William Hamilton's essay on the "Theory of Systems of Rays" contains the essence of all that is needed to calculate to a high degree of accuracy the aberration of such a lens.

But at that date photographic lenses were not thought of, and when Daguerre announced his invention in 1839 the work of Airy and of Hamilton was forgotten. Thus to quote, as I did lately in the Traill Taylor lecture, from the recent work of Dr. M. von Rohr.

"The important signification of Airy's writings for photographic optics does not seem to have been appreciated until a later date. Although they exercised an influence on English text-books, like that of Coddington, they seem unfortunately never to have become known in wider circles on the Continent. It appears, then, that the theoretical opticians of later years to whom his investigations into the astigmatic deformations of oblique pencils would have been of great interest did not base their work on that of Sir G. B. Airy," while Sir W. Hamilton's paper remained unnoticed by the optician until Finsterwalder directed attention to it, and another distinguished German, Prof. Thiessen, quite lately put his results into an accessible form.

There was a divorce between theory and practice in England. The importance of Daguerre's discovery was at once realised, and English opticians set to work with no small success to develop the lens and to make it perfect, and splendidly in many ways they performed their task; but the work was empirical. A certain amount of progress was possible, and was achieved, but without the guidance of well founded theory the progress could not be for long.

The learned Transactions of the Cambridge Philosophical Society and of the Royal Society of Dublin were perhaps the last places to which the practical optician would apply for help, and so it came about that because the opticians of another nation first recognised that a full knowledge of the action of a lens on the light that traverses it was a condition precedent to further truth, for some years past the great improvements in the products of the optician's skill which have taken place have had their origin mainly in Germany.

This brings me to our last example of the manner in which science and practice may combine to produce effects unattainable by either singly. But before dealing with this I would mention one great advantage which, until a few years ago, the English optician possessed in a special degree, an advantage to which much of the progress of our English lenses is undoubtedly due. The story of Gunand's invention of optical glass is deeply interesting. A poor carpenter, and later a watch-case maker, of Brenetz, in canton Neuchatel, he was born in 1740, and became at an early age interested in telescopes. Prompted by the desire to possess a pair of spectacles, he undertook to make the glass for the lenses. A little later, through M. Droz, a gentleman of the neighbourhood, he was allowed to examine one of Dolland's achromatic lenses, and learnt of the difficulty of obtaining the flint glass required. This he determined to make, and years of penury and unremitting toil followed, until at last he succeeded in casting discs sufficiently homogeneous to be used for optical work.

Fraunhofer persuaded him to migrate to Munich, but the venture was not a success. He returned to Switzerland, and again started glass making. After his death his son told the secret of the art to George Boutemps, a Frenchman, who some years later was brought to England by Messrs. Chance, and helped them to establish the optical glass works which for so long were practically the sole source of the supply of raw material for the optician.

Our catalogue to-day bears witness to the progress in glass manufacture that has taken place since Boutemps's time, and it is right to recognise the influence that progress has had on opticians' work.

But to return to our main subject. An optical convention in 1905 would be incomplete without some reference to the work of that master optician who a few months ago was taken from us, the more so since the work of Ernst Abbe affords perhaps the most striking illustration of the effects of the reasoned combination of theory and practice. A comparison of the statistics of the optical trade of Germany now and twenty years ago will suffice to prove this.

The story of the growth of the Jena industry has been told frequently, still I will repeat it in barest outline. Abbe, then a young man, had settled at Jena as a privat docent in 1863, and soon after Carl Zeiss, who then made microscopes of the ordinary class, applied to him for help in the development of the instrument. Abbe's task was a hard one; the theory of the microscope was at that date only partially understood, the corrections to the lenses were made by a rough trial and error method, and the results were doubtful. The first step was to solve a mathematical problem of no small difficulty, to trace the paths

of the pencil through the object glass. Abbe soon realised the defects of the ordinary theory. He found it necessary to apply the principles of the wave theory, the teaching of Young and Fresnel, to the problem, and was led in 1870 to the theory of microscopic vision which bears his name. His work was the direct outcome of that of Fresnel.

He soon realised that it followed from the mathematical theory that with the glass then at the optician's disposal no great improvement in the microscope object glass could be expected. Certain relations between the dispersion and refraction in the various lenses were requisite to secure achromatism, and no glass having these relations existed. An inspection of the instruments in our loan exhibition at South Kensington in 1876 confirmed this view, and he published it in a report in 1878 on the results of the exhibition:—"The future of the Microscope as regards its future improvement in its dioptric qualities seems to be chiefly in the hands of the glass maker."

The investigations of Petzval and of von Seidel led to a similar result with regard to photographic lenses. Von Seidel's work dates back to 1856–7, but his main paper was not written until 1880, after the date of Abbe's report, and was not published in full until 1898.

It follows from these investigations that with the glass then on the market it was impossible to make the field of a photographic lens at once flat and achromatic.

Thus the theoretical work indicated a bar to future progress which could only be removed by the manufacture of new glasses having certain definite properties. It is fitting to say that at an earlier date this fact had been recognised by our countrymen Mr. Vernon Harcourt and Prof. Stokes, who for some eight years previous to 1870 had endeavoured, but with scant success, to make the glass required.

Abbe was more fortunate; his report fell into the hands of Dr. Otto Schott, a glass maker of Witten, in Westphalia, who realised its importance. In 1881 Schott communicated with Abbe, and the next year he removed to Jena, and the firm of Schott and Partners was born.

In the first catalogue of the Jena Glass Works they write:—"The industrial undertaking here first brought into public notice and which has arisen out of a scientific investigation into the dependence between the optical properties and the chemical composition of solid amorphous fluxes was undertaken by the undersigned (Schott and Abbe) in order to discover the chemicophysical foundations of the behaviour of optical glass." The inquiry was aided by large grants from the Prussian Minister of Education. The practical result is seen in the catalogue of the Jena firm and the enormous export of German optical goods.

Nor is this all, for in virtue of the distribution of profits settled by the scheme of the Carl Zeiss Stifting, drawn up by Abbe some years ago and ratified by the Bavarian Government, the University of Jena alone has received a sum approaching 100,000*l*. Abbe's work at Jena is perhaps the most striking illustration of the way in which progress depends on the cooperation of science and experience. One could give statistics to illustrate the truth of this and the important effect it has had on German trade and prosperity. They are hardly necessary; the facts are patent, and their cause well known to all who care to inquire. We can progress too if we follow the path laid down for us of old by Newton, Young, Herschel, Airy, and the others of whom I have spoken.

EXHIBITION OF OPTICAL AND SCIENTIFIC INSTRUMENTS.

The exhibition of optical and scientific instruments which is being held during the present week at the Northampton Institute, Clerkenwell, E.C., in connection with the optical convention, presents many features of interest, and all who have had any experience in the use of an optical instrument, from the wearing of a pair of spectacles to the handling of an accurate spectrometer, will find something to repay the trouble of a visit to Clerkenwell, still the centre of the optical industry. While the number of actual novelties offered is not, perhaps, very large, there are few classes of instruments unrepresented, and though the names of certain important firms are conspicuously absent from the list of exhibitors, the exhibition as a whole may be taken as well representative of the activities of the British manufacturers of optical and other scientific instruments.

In the main of an optical character, the scope of the exhibition has been extended to cover such other scientific instruments as are usually manufactured by optical instrument makers. Meteorological instruments and thermometers, mathematical and drawing instruments and calculating machines, and laboratory apparatus generally, are thus included. Electrical measuring instruments, however, are not shown. It is for many reasons to be regretted that the exhibition has been confined to the work of British makers; a foreign section would have had much interest for the ordinary visitor, and would have been of great educational value both to the British manufacturer and his competitors; we understand, however, that the limitation was dictated by considerations as to space, and the necessity of restricting the magnitude of a somewhat novel undertaking.

In the catalogue which has been prepared in connection with the exhibition, the convention committee is to be congratulated on having produced a volume which should be of considerable value as well to the user of scientific instruments as to the firms whose instruments are there described. The volume is not confined to apparatus actually exhibited; the aim has been to provide a convenient work of reference generally descriptive of the productions of British firms, and in which particulars as to the types offered by different makers of any special instrument may be readily found. To this end the instruments have been arranged in classes, which are in many cases further subdivided, and in addition to a table of contents, an alphabetical list of exhibitors, with general information as to their manufactures, and an index of instruments have been provided. A short introduction to each class furnishes some particulars as to the instruments included thereunder, with notes as to recent advances in the mode of construction.

In class i., tools and materials, the most interesting exhibit is that of Messrs. Chance Bros., which includes some varieties of optical glass only quite recently produced by the firm, and not previously shown. Some special opal glass of low coefficient of expansion for speculum discs is also exhibited. Messrs. Jas. Powell and Sons, of the Whitefriars Glass Works, show specimens of glass for thermometers and other purposes. Tools for lens grinding, and exhibits illustrating processes of manufacture, are shown by Messrs. Geo. Culver and other firms.

Class ii., simple elements and instruments, includes some accurate glass work by Messrs. A. Hilger, while Lord Blythswood shows specimens of his diffraction gratings ruled on speculum metal, 14,400 lines to the inch, up to a length of 6 inches. Replicas of Rowland gratings, with spectroscopes of various forms in which they are employed, are shown by Mr. T. Thorp, of Manchester.

Class iii., astronomical instruments, and class iv., nautical instruments, are by no means representative of the best English work, and it is to be regretted that the catalogue is here so meagre.

In class v., surveying instruments, on the other hand, few firms of importance are omitted, and some excellent work is shown. In particular may be mentioned the Wells theodolite of Messrs. Elliott Bros., which embodies several novel features; Messrs. Joseph Casartelli and Son, of Manchester, also show instruments of somewhat special pattern. Messrs. W. F. Stanley, J. J. Hicks, and E. R. Watts and Son are well represented. The chief characteristics of the more modern instruments are the use of larger and more powerful telescopes, and the increased accuracy of graduation.

Class vi. is devoted to range finders and heliographs, and the exhibits of most interest are the naval and field range finders of Messrs. Barr and Stroud, and the stereoscopic range finder of Prof. Geo. Forbes. Messrs. Ross, Ltd., show specimens of their new variable power gun sighting telescopes, in which by a simple device the power can be altered while the image remains always in focus on the cross wires.

Class vii. includes meteorological instruments and thermometers, and most of the well known makers have sent exhibits. In class viii., spectacles and eyeglasses, the exhibits are also sufficiently representative of the best English

work. An historical collection of no little interest is shown by Mr. M. W. Dunscombe, of Bristol.

In class ix., small telescopes and binoculars, are exhibited various patterns of prism binoculars by Messrs. Aitchison, Dallmeyer, Ross, Ltd., &c. Messrs. Aitchison show also a field glass of novel type with a body machined from a solid casting, focusing being effected by moving each object glass in its own tube.

In class x., microscopes and accessories, the catalogue furnishes a very complete account of the English microscope as produced by the best makers, including binocular microscopes and various forms of instrument for special purposes. Photomicrographic cameras are shown by Messrs. Beck, and Ross, Ltd. Information of interest with regard to different types of photographic lenses is given in class xi., though too much space is perhaps devoted in the catalogue to illustrations of camera bodies.

In the careful classification and selection of instruments to illustrate the various types, class xii., optical projection apparatus, appears to us to be the most successful in the catalogue. The class includes an exhibit by Messrs. Chance Bros. of a complete lighthouse optical apparatus of the fourth order. Other exhibits of interest are Mr. R. W. Paul's projector lamps, the triple rotating lantern of Messrs. Newton, and animatographs by Messrs. Paul, the Prestwich Manufacturing Co., and J. Wrench and Son.

In class xiii., apparatus for optical measurement, some new optical benches are shown by Messrs. Aitchison and Beck, and there are interesting exhibits from the Cambridge Scientific Instrument Co. and Messrs. Hilger. A half-shadow polarimeter is shown by Prof. Poynting, the half-shadow field being produced by the tilting of two glass plates forming a V between the polariser and analyser.

Under photometric apparatus the Ediswan Co. show specimens of Prof. Fleming's large bulb standard lamps, and various forms of photometer are exhibited by Messrs. Alex. Wright. Class xv. is devoted to ophthalmic apparatus, and includes a novel form of ophthalmoscope of British design and construction. The Cambridge Scientific Instrument Co. and Messrs. Griffin show laboratory apparatus under class xvi. Under class xvii., mathematical and drawing instruments, some new forms of slide rule are shown, including one with additional slides by Messrs. Davis, of Derby, and an optical slide rule with reciprocal division for determination of conjugate foci, &c., by Mr. A. Salomon, of Huddersfield. An arithmometer of English make is exhibited by Mr. S. Tate, and an adding machine by the Burroughs Adding Machine Co.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Among the twelve distinguished men who will receive honorary degrees on June 14 only two are connected with scientific work. These are Commander R. F. Scott, R.N., of the *Discovery*, and Colonel Sir Francis E. Younghusband, K.C.I.E. The latter has been appointed Rede lecturer, and has chosen as his subject "Our True Relationship with India." The lecture will be delivered in the Senate at 11.30 a.m. on Saturday, June 10.

Mr. L. A. Borradaile, of Selwyn College, who is well known for his researches on the crustacea, has been appointed assistant secretary for lectures to the local examinations and lecture syndicate.

A university lectureship in mathematics will shortly be vacant owing to the resignation of Mr. G. B. Mathews, F.R.S., of St. John's College.

The special board for biology and geology has nominated Mr. J. J. Lister, Fellow of St. John's College, to occupy the university table at the laboratory of the Marine Biological Association at Plymouth for one month during the present year.

In spite of the efforts of the master of Pembroke, Prof. Ridgway and others to bring the work of the studies and examination syndicate to an end, the Senate decided by 112 votes to 99 that its deliberations should be continued. It seems evident that a majority of residents is in favour of some change.

The syndicate entrusted with the building of the new medical schools has exceeded the sum granted by Grace of the Senate by 2571*l*. 15*s*. 6*d*. It is now asking for authority to pay this amount, and for 020*l*. for the completion and fitting of the Humphry Museum, and 380*l*. for extra fittings and furniture in the departments of surgery, midwifery, medicine, pharmacology, and pathology.

THE *Pioneer Mail* states that a grant of 10,000 rupees has been made to the Victoria Diamond Jubilee Technical Institute of Lahore for buildings and appliances. A permanent grant of 100 rupees a month has also been made, and the assistance thus given will enable the governors to complete the equipment for the teaching of practical and applied chemistry.

AT a meeting of the School Nature-Study Union held at the College of Preceptors on Friday, a paper was read on the training of teachers for nature-study by Miss R. Lulham. In it the necessity for a proper ground work was brought out, and during the discussion which followed a resolution was passed urging upon the London County Council the need of providing classes for those who have to teach nature-study, and suggesting that a wild garden for their benefit should be established in at least one of the London parks, in which the botanic gardens arranged for the students of systematic botany have already proved so useful.

WE have received the first number of the *University Review*, which is published by Messrs. Sherratt and Hughes at 6*d*. net. Dr. Bryce contributes an introductory note on the university movement, and among other articles dealing with many aspects of higher education may be mentioned one by Prof. Arthur Schuster, F.R.S., on "Universities and Examinations," and another by Sir Oliver Lodge, F.R.S., on "Questions for Discussion." Prof. Schuster formulates briefly what the aims of an ideal university should be, and proceeds to divide its work into two parts. These are the acquisition of knowledge and the power of applying it. The second part of the work of the university is the higher, and is what is required for success in life. Prof. Schuster says that it can be taught, and therefore should be taught, in the university, but that this power of applying knowledge cannot be tested satisfactorily by examination. He then considers exhaustively the function of examinations, and shows what they are capable of doing and the qualities they are incompetent to gauge. He concludes by remarking that when a student "has shown that he deserves a degree, it is right and proper that an opportunity shall be given him to develop his special powers and to distinguish himself." Prof. Schuster makes a proposal to secure this by giving a year which is absolutely at the student's disposal to be used under the guidance of his teachers as he thinks fit. Sir Oliver Lodge discusses the possibility of introducing a change in the "time of year when examinations should be held:—whether candidates should be examined directly lectures cease, and before Session ends; or whether they should be given time for revision and digestion, and perhaps oblivion, and be examined just before a new Session commences." The review also supplies full information of current events in British and foreign universities.

SOCIETIES AND ACADEMIES.

LONDON.

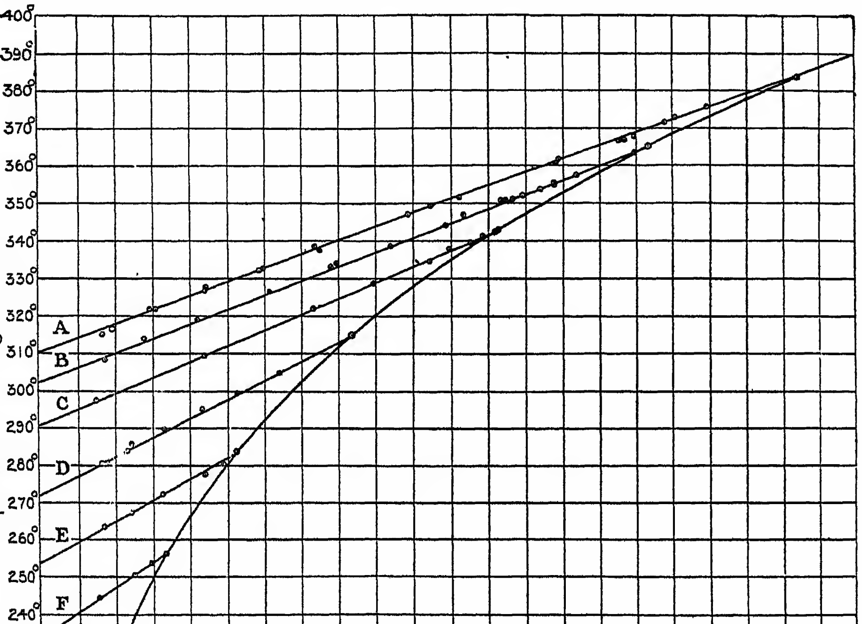
Royal Society, March 30.—"The Determination of the Specific Heat of Superheated Steam by Throttling and other Experiments." By A. H. **Peake**. Communicated by Prof. Ewing, F.R.S.

This paper is an account of original investigations undertaken to determine the specific heat of superheated steam. Two methods have been followed:—(1) the throttling or wire-drawing of steam to obtain the law connecting the variation of temperature with pressure, for constant total heat; (2) the direct heating of a current of steam by electrical means.

An account of an investigation on the same lines as method (1), by Mr. J. H. Grindley, was published in the *Philosophical Transactions of the Royal Society*, A, vol.

cxciv. pp. 1 to 36. The results here given differ from those obtained by Mr. Grindley in one important particular. Mr. Grindley came to the conclusion that steam taken from a separator contained a definite proportion of suspended moisture, because when he caused such steam to expand through an orifice to a slightly reduced pressure the steam did not become superheated, but its temperature fell to that corresponding to saturated steam at the new pressure. In the research here described, however, it was found that steam taken from a separator and reduced in pressure in the slightest degree by wire-drawing became superheated. This result was only obtained after a considerable amount of experimental work had been done, and a number of improvements made in the apparatus as first constructed.

The experimental results obtained in the throttling experiments are represented in the accompanying figure. The curves A, B, C, D, E, and F show the connection between the temperature and pressure of superheated steam for constant total heat. The method of obtaining



each of these curves was as follows:—The pressure of steam in the separator was maintained constant at the point where the constant total heat curve meets the curve which connects the pressure with temperature for saturated steam; the pressure on the low-pressure side of the orifice could be regulated by means of a wheel valve, which allowed the steam to escape at any desired rate. This lower pressure was adjusted to various values, and the temperatures corresponding were observed when the conditions had become steady. By plotting these results points were obtained which enabled the curve to be drawn.

The total heat corresponding to each of the curves was obtained from Regnault's tables for saturated steam, and the specific heat at constant pressure calculated for various pressures. The specific heat as thus calculated was found to increase rapidly with increase of temperature from 0·43 at 230° F. to 1·0 at 350° F. This apparent increase in the specific heat led the author to suspect the accuracy of Regnault's tables, and caused him to turn to the direct heating method, with the result that he is now convinced that Regnault's tables are not sufficiently accurate for the purposes of these calculations, and that a great degree of accuracy would be necessary before such was the case.

In method (2) the rise in temperature was observed in steam flowing at a measured rate, due to the heat imparted by an electric current, and the specific heat calculated from the formula

$$K_p = \frac{\text{electrical input in watts} \times 0{\cdot}236}{\text{grams of steam passing per sec.} \times \text{temp. rise}\ {}^\circ\ \text{C.}}$$

The connection between grams of steam passing per minute and the input of electrical energy in watts for a definite rise in temperature was obtained for rates of flow differing over a considerable range; the points thus obtained were plotted on squared paper, and were found to lie on a straight line which did not pass through the origin, but cut the watts ordinate at a height corresponding to the radiation loss expressed in watts.

The difficulty experienced in keeping all the conditions constant during the long time necessary for a complete set of points was always considerable. Numerous experiments were carried out, but the results varied too much amongst themselves to enable conclusions to be drawn as to the manner in which the specific heat may vary with pressure or temperature, except that any such variation must be small, and by no means of the order indicated by the results of the throttling experiments based on Regnault's tables.

The mean value of the specific heat of superheated steam at constant pressure obtained from the most satisfactory experiments was 0·46.

May 11.—"A Study of the Process of Nitrification with Reference to the Purification of Sewage." By Dr. Harriette **Chick**. Communicated by Prof. Marshall Ward, F.R.S.

The process of nitrification during sewage purification was studied by means of small experimental filters erected in the institutes of hygiene in Vienna and Munich.

The oxidation of sewage passing through the filters was investigated during the maturing period, and also when the filters were mature, a special study being made, chemically, of the oxidation of the nitrogen from the ammoniacal form to that of nitrites and nitrates, and of the distribution of these processes both in time and space.

Nitrification was traced to the activity of two sets of organisms, the first of which oxidised ammonia to nitrous acid, and the second completed the oxidation to nitric acid. These bacteria were found to differ only very slightly from those isolated from the soil by Winogradsky, thus confirming the recent results of Schultz-Schultzenstein. The activity in sewage filters of these organisms, which are very sensitive to the presence of organic matter, requires explanation, and various explanations are considered, based upon experimental foundation.

The theory of previous physical absorption of ammonia upon the surface of the filtering material and subsequent nitrification was found to be unsupported by experiment; nitrification is rather to be considered as a very rapid biological process, requiring only the time taken by the sewage to trickle through the filter.

Linnean Society, May 4.—Prof. W. A. Herdman, F.R.S., president, in the chair.—The botany of Gough Island, part i., phanerogams and ferns: R. N. **Rudmose-Brown.** Gough Island, or Diego Alvarez, lies in the mid South Atlantic, lat. 40° 20′ S., long. 9° 56′ 30″ W., and may be regarded as the most outlying member of the Tristan da Cunha group, a small island between seven and eight miles long, and half as wide, rising to a height of 4000 feet. It has been occasionally visited, but never permanently inhabited. The chief features of the vegetation are the tree *Phylica nitida* and the tree-fern *Lomaria Boryana*. Four of the seventeen species of phanerogams are almost certainly introduced, while two are new to science, a species of Cotula and an Asplenium. The Scottish Antarctic Expedition lay off the island for three days in April, 1904, but owing to high sea landing was only practicable on one day, when the materials for the present paper were collected.—The study of vegetation: its present condition and probable development: Prof. A. G. **Tansley.** The word œcology, introduced by Prof. Haeckel, means the study of the vital relations of organisms to their environment, and by Prof. E. Ray Lankester was termed bionomics. Restricting his remarks to a special branch of the subject, the author proceeded to consider the plant-association as the unit, the great fact being the association of plants under definite conditions of environment. Instances were given of sets of plants found in meadows, woods, cultivated fields, moors, and dunes.—Schizopoda captured in the Bay of Biscay during a cruise of H.M.S. *Research*: E. W. L. **Holt** and W. M. **Tattersall,** with an appendix dealing with the distribution statistically by Dr. G. H. **Fowler.** The paper forms part v. of the series on Biscayan plankton. Ten genera and eleven species were described; of these one species is new to science, and one, previously known from a single example, is represented by eight specimens. All the commoner forms are epiplanktonic, but of these some are represented by scattered specimens from greater depths. *Euphausia pellucida,* essentially epiplanktonic, with a centre of distribution about 50–75 fathoms, seems to show a marked vertical oscillation, rising by night and sinking by day: it was plentiful in bright moonlight; by day scattered specimens occurred between 250 and 100 fathoms. *Meganyctiphanes norvegica,* caught in small numbers and on few occasions, was only captured by night, never by day at any depth whatsoever. Messrs. Holt and Tattersall suggest that this species is sufficiently sharp-sighted to see and avoid a net by daylight, even at a depth of 100 fathoms. *Nematoscelis megalops,* with the same distribution as *Euphausia pellucida,* showed a less clearly marked oscillation.

Anthropological Institute, May 9.—Dr. A. C. Haddon, F.R.S., vice-president, in the chair.—Some tribes of the Uganda Protectorate: Lieut.-Colonel C. **Delmé-Radcliffe.** The author described the customs and habits of the natives with whom he came in contact, including the Kavirondo and other tribes on the Victoria Nyanza, and the Acholi in the Nile Province. The paper was illustrated by numerous lantern slides, illustrating the peoples, animals, and scenery, and by a large and interesting collection of ethnographical specimens from the Protectorate.

Challenger Society, May 10.—Prof. d'A. W. Thompson, C.B., in the chair.—A new species of Tuscarusa from the North Atlantic: Dr. **Wolfenden.**—Observations on the temperature and salinity of the water of the North Atlantic, made during two cruises of Dr. Wolfenden's yacht *Silver Belle* during the summers of 1903 and 1904: Dr. H. N. **Dickson.** In 1900–2 much valuable work had been done by Dr. Wolfenden in the Færöe Channel, but as this area lay within the field of the International Council for the Study of the Sea, he worked in 1903 farther out in the Atlantic, to the west of Ireland, and at the entrance to the Færöe Channel south of the Wyville-Thomson Ridge, the observations connecting directly with those of the International Council in the Channel itself and in the Norwegian Sea during the August cruises. The work in 1904 was more directly concerned with the general oceanic movements of Atlantic waters; a line of soundings was run from the south-west of Ireland to the Azores, thence into the Mediterranean through the Straits of Gibraltar, and thence to the English Channel. Dr. Dickson illustrated the observations by diagrams of temperature and salinity along the sections, and discussed the considerable light thrown on the behaviour of the easterly drift on reaching the shores of Europe, the exchange of waters between the Atlantic and the Mediterranean, the volume of current in the straits, and the extension in the Atlantic of Mediterranean water of high temperature and salinity.

Geological Society, May 10.—Mr. R. S. Herries, vice-president, in the chair.—The geology of Dunedin (New Zealand): Dr. P. **Marshall.** A detailed account of the petrography of the district was given. The age of the oldest rocks seen, mica-schists, is not definitely known. They are followed by Tertiary sandstones and limestones. Fine, plant-bearing shales succeed unconformably, and upon these, again, rests a light scoria-bed. The igneous rocks next described cover them. These rocks include an ill-exposed, gold-bearing syenite, a diorite, lavas, rhomb-porphyry, tinguaite, hypabyssal trachydolerite, a teschenite-dyke, and trachyte. Trachytoid phonolites occur as inter-bedded sheets. The andesites are characterised by hornblende and augite. Dolerites of two principal types occur in dykes, one type being the commonest of all the rocks in the area. A considerable series of chemical analyses follows, showing that the silica-percentage varies from 66 in the Portobello trachyte to 44·84 in one of the dolerites. The relative ages of the volcanic rocks are worked out so far as possible.—The Carboniferous limestone of the Weston-super-Mare district: T. F. **Sibly.** The Carboniferous limestone of the Weston-Worle ridge includes part of the Syringothyris-zone (C), extending from the "laminosa-dolomites" upwards, and part of the Seminula-zone (S). While the dip of the rocks of the ridge is towards the south, a reversed fault throws the Syringothyris-beds on the south against the Seminula-beds to the north, and the latter rocks are over-folded on the north side of the fault. The lower part resembles the equivalent part of the Clevedon sequence, and indicates shallow-water conditions; the upper part of C resembles the corresponding part of the Burrington section, and indicates the predominance of a Mendip-facies. The Woodspring ridge shows a sequence exactly similar to that of Clevedon. There were two periods of volcanic activity, one of which occurred at the close of Zaphrentis-time and the other early in Syringothyris-time.

Physical Society, May 12.—Dr. C. Chree, F.R.S., vice-president, in the chair.—A simple method of determining the radiation constant, suitable for a laboratory experiment: Dr. A. D. **Denning.** The apparatus consists of a hemispherical copper cap to the outside of which is affixed a jacket through which steam or water can be passed. The receiving surface consists of a silver plate, and the rate of rise of temperature of the plate is measured by means of a silver-constantan thermo-junction. When performing the experiment, a non-conducting pad is placed between the hemisphere and the silver disc until the temperature of the jacket is uniform. Then the pad is slid out, and the deflections of the galvanometer in the thermo-junction circuit are noted every few seconds. By plotting these deflections on a curve the initial slope of the curve, *i.e.* the initial rate of rise of temperature of the silver disc, is obtained; and from this, knowing the constants of the disc, &c., the radiation constant can be calculated.—A bolometer for the absolute measurement of radiation: Prof. H. L. **Callendar.** It is now generally agreed that the electric compensation method, in which the heat received by radiation on a metallic strip is determined by measuring the electric current required to produce the same rise of temperature in the strip, is the most satisfactory and accurate method for absolute measurement. In the practical application of the bolometric method for the absolute measurements of solar radiation, the author has introduced certain modifications suggested by experience in platinum thermometry, with the object of securing (1) temperature compensation, so that the zero remains constant in spite of changes in the surrounding temperature; (2) conduction compensation, so that loss of heat by conduction at the ends of the strips may not affect the readings; (3) accurate measurement of the area of radiation absorbed. Comparisons have been made between

the bolometer, in which the platinum strips are directly exposed to radiation, and one of the author's ordinary sunshine receivers enclosed in a glass bulb, in order to determine the effect, if any, of the glass bulb in selective absorption. The values of the reduction constant obtained for the glass receiver showed no certain variation over a wide range of quality of radiation, from sunshine or arc-light down to a dull red heat. This result is probably to be attributed to a self-compensating action of the glass bulb, which radiates to the enclosed coils precisely those rays which it absorbs.—Results of experiments carried out at Crompton's works at Chelmsford, by Mr. C. H. Wright, on the possibility of using the resistance of a conductor heated by an alternating electric current as a measure of the current: W. H. **Price.**

Zoological Society, May 16.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—Examples of a new golden mole obtained in connection with Mr. C. D. Rudd's exploration of South Africa: O. **Thomas.** It is proposed to call the mole *Amblysomus corriae*, sp. n.—Microscopic slides of *Lankesterella tritonis*, a hæmogregarine parasitic in the blood-corpuscles of a newt, *Triton cristatus*: H. B. **Fantham.** This parasite was recently found by Mr. A. S. Hirst and the exhibitor, and their observations had since been independently confirmed by Dr. A. C. Stevenson.—A contribution to the knowledge of the encephalic arterial system in Sauropsida: F. E. **Beddard.**—Criticisms of the Hon. Walter Rothschild's proposed classification of the anthropoid apes: Sir H. H. **Johnston.** The author was disposed to agree with Mr. Rothschild's classification of the African apes, but suggested that the proper transcription of the native name for the bald chimpanzee should be *nkulunkamba* instead of (as Du Chaillu wrote it) *kooloo-kamba*. He, however, could not agree with Mr. Rothschild's proposed change of the generic name of the orang from Simia to Pongo, and although considering him right in applying the former name, at present used for the orang, to the chimpanzees, he was of opinion that either Satyrus or Pithecus was a far preferable name to Pongo for the orang. He concluded the paper with a list of words used in several African languages for the name of the chimpanzee, and with a *précis* of the history of European knowledge of the anthropoid apes down to the eighteenth century.—Some species of bats of the genus Rhinolophus: K. **Andersen.** The author showed the progressive evolution from the Austro-Malayan *R. simplex* (allied to *megaphyllus*), through a long series of Oriental forms, to the W. Palæarctic *R. ferrum-equinum*, and a similar chain from the Oriental *R. lepidus* (allied to *minor*) to the W. Palæarctic *R. blasii* and *R. euryale*. *R. hipposiderus* was traced back to the Oriental *R. minor*. A slight difference between the British colony of *R. hipposiderus* and the central European form of the same species was pointed out. All the Ethiopian species of Rhinolophus were shown to be of Oriental origin.—Results of observations on the stridulating-organs and descriptions of five new species (two of which were referred to new genera) of the hemipterous family Halyinæ: Dr. E. **Bergroth.**—On the anatomy of limicoline birds, with special reference to the correlation of modifications: Dr. P. C. **Mitchell.** The paper dealt with the anatomy, chiefly muscular, of Charadriidæ, Chionididæ, Glareolidæ, Thinocoridæ, Œdicnemidæ, and Parridæ.—Results of observations made upon a female specimen of the Hainan gibbon (*Hylobates hainanus*), now living in the society's gardens: R. I. **Pocock.**

PARIS.

Academy of Sciences, May 22.—M. Troost in the chair.—New experiments in experimental parthenogenesis in Asterias: Yves **Delage.** Additional proof is given of the fact that it is not an increase in the osmotic pressure alone which determines parthenogenesis, several of the reagents employed, manganese chloride, sodium phosphate, &c., acting as well, if not better, when the total concentration of the mixture is lower than that of sea water. Attention is directed to the marked action of solutions of manganese chloride, a salt which is not present in sea water.—Magnetic hysteresis produced by an oscillating field superposed on a constant field. Comparison between theory and experiment: P. **Duhem.** The author compares the results obtained by him in a theoretical study recently published with some experimental results of M. Maurain, and shows that his theoretical conclusions are completely confirmed.—On the voyage of the *Princesse Alice*: the **Prince of Monaco.** A sketch is given of the work attempted in oceanography, bacteriology, chemical biology, zoology, and the meteorological exploration of the upper atmosphere by means of kites.—On a condition of convergence of Fourier's series: Henri **Lebesgue.**—On minimal curves: E. **Vessiot.**—On the compressibility of different gases below atmospheric pressure and the determination of their molecular weights: Adrien **Jaquerod** and Otto **Scheuer.** The compressibility of several gases has been measured at 0° C. for pressures between 400 mm. and 800 mm. of mercury, and for ammonia and sulphur dioxide for pressures between 200 mm. and 400 mm. From the measurements the coefficient of deviation from Boyle's law has been determined, and this has been applied to the formula of D. Berthelot for the limiting density of gases and the estimation of their molecular weight. The molecular weights calculated agree with those obtained by the best analytical methods with the exception of nitrogen compounds, for which an atomic weight of 14·01 must be assumed.—The atomic weight of nitrogen deduced from the ratio of the densities of nitrogen and oxygen: Philippe A. **Guye.** From a consideration of the whole of the experimental data available, the mean value $N = 14{\cdot}009$ must be regarded as the most probable value for the atomic weight.—On the fusibility of the mixtures of antimony sulphide formed with cuprous sulphide and mercuric sulphide: H. **Pélabon.**—The equilibrium between acetone and hydroxylamine hydrochloride: Philippe **Landrieu.** This equilibrium has been previously studied by means of the acid set free during the reaction, but owing to the rapidity with which the equilibrium is displaced this method is not trustworthy. In the present paper the reaction is followed by calorimetric studies.—Physicochemical researches on hæmolysis: Mlle. P. **Cernovodeanu** and Victor **Henri.**—The action of the metal ammoniums on the polyatomic alcohols: E. **Chablay.** The alcohol is dissolved in liquid ammonia and is then acted on by the solution of the alkali metal, sodium or potassium, also dissolved in ammonia, and the result of the reaction washed several times with liquid ammonia at −40° C. In this way one of the hydroxylic hydrogen atoms of the alcohol is replaced by potassium (or sodium), the alcohols studied being mannite, erythrite, and glycerol.—On benzhydroxamic and dibenzhydroxamic acids: R. **Marquis.**—A new method of preparing mesoxalic esters: their condensation with cyanacetic esters: Ch. **Schmitt.** The corresponding malonic esters are treated with nitrous fumes, descriptions being given of the preparation of the methyl and ethyl esters. These condense with cyanacetic esters in the presence of piperidine, one or two molecules of the cyanacetate entering into the reaction according to the experimental conditions.—The basicity of pyranic oxygen. Double halogen salts of some metals and dinaphthopyryl: R. **Fosse** and L. **Lesage.** The group dinaphthopyryl,

$$-\mathrm{CH}\begin{matrix}\diagup \mathrm{C_{10}H_6} \diagdown \\ \diagdown \mathrm{C_{10}H_6} \diagup\end{matrix}\mathrm{O},$$

possesses basic properties attributable to tetrabasic oxygen strikingly analogous to an alkaline metal, and the present communication gives details of the preparation of several double salts of this radical.—On some circumstances influencing the physical state of starch: J. **Wolff** and A. **Fernbach.**—Researches on animal lactase: Ch. **Porcher.** It is shown that ether saturated with water is capable of extracting from the intestines of certain animals considerable quantities of lactase.—Contribution to the study of histological staining substances: G. **Halphen** and André **Riche.** The albuminoid substances in animal tissues preserved in formol solutions are profoundly altered, and the methods of staining to be employed require considerable modifications.—On some minerals of Djebel-Ressas (Tunis): L. **Jecker.**—Variation in the histological characters of leaves in the galls of *Juniperus Oxycedrus* from the Midi and Algeria: C. **Houard.**—On the biology of *Melampyrum pratense*: L. **Gautier.**—On the transformations of the nitrogenous materials in seeds in the course of maturation: G. **André.**—Observations on the fibrous intersections of

CALCUTTA.

Asiatic Society of Bengal, May 3.—Contributions to Oriental herpetology, iii., notes on the Oriental lizards in the Indian Museum (part ii.), Lacertidæ, Scincidæ, and Dibamidæ: Dr. N. **Annandale.** Three new Indian skinks are described, and four imperfectly diagnosed species re-described, while one, *Lygosoma pulchellum,* is added to the fauna of Burma. Notes on other examples of the family and of the Lacertidæ are given, based on the late Dr. J. Anderson's collection from N.W. Asia and the late Prof. J. Wood-Mason's from Sinkip Island and Malaya, as well as the extensive Indian, Burmese, and Persian collections in the museum. A revised list of the species recorded from India, Burma, and Ceylon is appended, with their distribution within these limits.—Materials for a flora of the Malayan Peninsula, No. 16: Sir G. **King** and J. S. **Gamble.** The present contribution to these materials contains the account of the genus Psychotria required to conclude the joint account by the authors of the natural order Rubiaceæ commenced in part xiv. and continued in part xv. of this series. This account of Psychotria comprises descriptions of 26 completely represented and 3 imperfectly known species; of these, 11 species are new to science. In addition, this fasciculus contains accounts, for which the authors are jointly responsible, of several natural orders.

DIARY OF SOCIETIES.

THURSDAY, JUNE 1.

ROYAL INSTITUTION, at 5.—Electro-magnetic Waves: Prof. J. A. Fleming, F.R.S

THURSDAY, JUNE 8, 1905.

A MANUAL OF QUATERNIONS.

A Manual of Quaternions. By Prof. Charles Jasper Joly, F.R.S. (London: Macmillan and Co., Ltd., 1905.) Pp. xxvii+320. Price 10*s.* net.

PROF. C. J. JOLY'S "Manual of Quaternions" is an important addition to the literature of the subject. It at once takes rank with Tait's "Treatise" as an eminently serviceable exposition of Hamilton's great calculus.

Hamilton's own works, the "Lectures" and the "Elements," are in their way inimitable. Unfortunately, their style is not suited to the average student eager to acquire a working knowledge of the mathematical method developed in them. Tait alone of the younger contemporaries of Hamilton seemed to have been able to appreciate the "Lectures"; but he himself used to relate how, as he laboriously read through the first six, he began to despair of his own powers. There seemed to be such diffuse discussion, and withal so little apparent progress. But the seventh lecture came like a transformation scene. Every page displayed new beauties, every paragraph disclosed the marvellous power and variety of the method. From it Tait drew his inspiration, and proceeded to enlighten the world as to the meaning and purpose of the quaternion.

To the student who has grasped the essentials of the method Hamilton's second volume, the "Elements," will always prove a happy hunting ground; but experience has shown that its very completeness acts as a deterrent. In the much smaller treatise written by Tait, the important practical aspects of quaternions are more rapidly though less logically developed, and the chief value of Tait's work lies in his characteristic treatment of dynamical and physical problems. It has been long felt, however, that a good working manual of quaternions was needed, by use of which the mathematical student could come quickly into touch with all that is essential in the calculus. This is what Prof. Joly has endeavoured to supply.

For reasons clearly explained in the preface, the author has (reluctantly, he confesses) forsaken the Hamiltonian approach. Instead of developing the calculus logically from the definition of a quaternion as the ratio of two vectors, he defines independently the quantities $S\alpha\beta$ and $V\alpha\beta$, and then writes the product $\alpha\beta$ as equal to the sum of these two. The student must, of course, take on trust that there is some good reason for defining $S\alpha\beta$ as *minus* the product of the length of one vector into the length of the projection of the other upon it. This is, at root, the peculiarity of Hamilton's system which troubled O'Brien nearly sixty years ago, and has not ceased to trouble occasional critics since. There is a kind of notion hovering about in some minds that the positive sign in algebra is more natural than the negative sign, the truth being, of course, that the one necessarily implies the other. It is to be feared, however, that this apparently arbitrary assumption of the negative sign in translating $S\alpha\beta$ into ordinary trigonometrical notation (Clifford calls it a *convention*) will puzzle many a student. Prof. Joly soon gives the reason for the negative sign, though not quite so definitely as might be desirable; but it is questionable if its full significance will be appreciated until considerable progress has been made in acquiring quaternionic skill. The reader is advised to exercise a strong faith, and to proceed nothing fearing. If he persevere he will soon get out of the valley of the shadow of the negative sign.

It is possible that some critic may regard this forsaking of Hamilton's logical basis as a confession of weakness. But this is not so. The weakness is in the average student, for whom a somewhat simple intellectual diet must be prepared in the hope that the mental digestion may be strengthened sufficiently to assimilate the strong Hamiltonian food which Prof. Joly serves up a little later. The truth is that very few students are able to appreciate to the full an absolutely logical argument until they have a certain amount of practical knowledge imparted to them more or less by authority.

So far as the *principle* of the method is concerned, Prof. Joly ranges himself at first on the side of those vector analysts who neglect the quaternion. But it is only for a couple of pages at the beginning of chapter ii. On p. 8 the important formula

$$(\alpha\beta = S\alpha\beta + V\alpha\beta)$$

is introduced as a definition of the quaternion, and the quaternion is never afterwards lost sight of. Its fundamental importance and analytic value are in evidence on every page. It must be admitted that by this line of approach the reader is rapidly brought into touch with the essential elements of the subject. There is, nevertheless, a certain arbitrariness which is not satisfying to the mind, nor is it clear when all is done what is really fundamental. A critically minded student might possibly be inclined to say, Why not define $S\alpha\beta$ as *plus* the product of the lengths of the vectors into the cosine of the angle between them, and then define the quaternion $\alpha\beta$ by the formula $V\alpha\beta - S\alpha\beta$? At first sight it seems to amount to the same thing, and yet, as will be found on trial, it leads to a system clothed in quaternion garments, but more like the fabulous ass in the lion's skin than the real lion.

Having thus established in chapter ii. the fundamental properties of the quaternion, Prof. Joly rapidly runs over certain important transformations of vector products and ratios (chapters iii. and iv.), and simple applications to the geometry of the straight line, plane and circle (chapters v. and vi.). Then follow, treated in separate chapters, differentiation, linear vector functions, quadric surfaces, and the geometry of curves and surfaces. Here the *power* of the calculus asserts itself strongly. Numerous examples are supplied throughout for the student to work upon and develop his analytical skill. In subsequent chapters dynamical problems of various kinds are taken up—such as astatic equilibrium, screws and wrenches, strains, central forces, constrained motion, motion of a rigid body, and the like. A valuable and well arranged chapter on the operator ∇ treats of heterogeneous strain, spherical harmonics, hydrodynamics, elasticity, electromagnetic theory, and wave propagation generally. The

treatment is by no means superficial, and is in many places highly condensed. It is all done in forty-two pages, a remarkable testimony to the compactness of quaternion notation and the brevity of quaternion proofs. In chapter xvii., on projective geometry, Prof. Joly gives his own interesting extension, in which a new interpretation is assigned to the quaternion, and he concludes in chapter xviii. with quaternions generalised so as to be applicable to space of any number of dimensions.

There can be no question as to the high merits of the "Manual of Quaternions." It is a worthy companion volume to the master's own great works. Like the "Elements" of Hamilton and the "Elementary Treatise" of Tait, it is characterised by the extraordinary range of mathematical subjects which come within its scope. It is not merely the substitution of one symbol for three or one for four which makes this condensation possible, for that, after all, is a question simply of notation. But the quaternion calculus rejoices in the possession of two remarkable operators, the linear vector function ϕ and the vector differentiator ∇. They operate singly and in combination according to laws which naturally evolve themselves from the fundamental laws of the calculus. They can be linked together in an endless variety of ways, and go far to give to Hamilton's quaternions a flexibility, power, and pictorial compactness not possessed by any other general method which is directly applicable to problems of mathematics pure and applied. These features are exquisitely brought out in Prof. Joly's "Manual." C. G. K.

SOME MEDICAL WORKS.

(1) *New Methods of Treatment.* By Dr. Laumonier. Translated from the second revised and enlarged French edition, and edited by Dr. H. W. Syers. Pp. xvii+321. (London: Constable and Co., Ltd., 1904.) Price 7s. 6d. net.

(2) *The Surgery of the Diseases of the Appendix Vermiformis and their Complications.* By W. H. Battle and E. M. Corner. Pp. xi+208. (London: Constable and Co., Ltd., 1904.) Price 7s. 6d. net.

(3) *Clinical and Pathological Observations on Acute Abdominal Diseases.* (The Erasmus Wilson Lectures, 1904.) By E. M. Corner. Pp. 98. (London: Constable and Co., Ltd., 1904.) Price 3s. 6d. net.

(4) *A Short Treatise on Anti-Typhoid Inoculation.* By Dr. A. E. Wright. Pp. x+76. (London: Constable and Co., Ltd., 1904.) Price 3s. 6d. net.

(5) *The Suppression of Tuberculosis.* By Prof. E. von Behring. Authorised translation by Dr. Charles Bolduan. Pp. v+85. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1904.) Price 4s. 6d. net.

(1) EVERY year a multitude of substances, chiefly synthetic, is introduced, every one being extolled as a certain cure for this or that ailment. By good fortune one of them is now and then found to be of real value, and for a time at least finds a place in the "aramentaria medica," but the majority in a year or two pass into oblivion. Similarly new modes of treatment come and go, most of them being of little worth. But the medical practitioner is expected to know of all these medicinal substances and vagaries of treatment, and must be prepared to employ any one of them at the suggestion of some faddist who happens to consult him. From this point of view the first book on our list may be a useful guide, but otherwise one would be inclined to ask, *cui bono?* Some of the substances included in the volume are by no means new, *e.g.* thyroid, guaiacol, and the antitoxic sera, while others which have a greater claim to novelty, and are, moreover, of real value, such as aspirin, acetozone, urotropine and cystamine, and purgen, are omitted. In dealing with tetanus antitoxin, no mention is made of injection into the spinal cord or nerve trunks. As regards phosphorised principles, lecithin, glycerophosphates, &c., which have of late been extolled in wasting diseases and nervous affections, the administration of a couple of eggs a day would probably be of far greater benefit than any of the medicinal preparations of these substances.

(2) Messrs. Battle and Corner give a succinct account of the anatomy, pathology, symptoms, and treatment of that common and fashionable malady appendicitis which may be safely recommended as a guide for the medical practitioner. The origin and function of the vermiform appendix are discussed; that little blind tubular appendage of the bowel inflammation of which gives rise to so much trouble. The appendix has usually been regarded as a vestigial structure and useless in function, but the researches of Mr. R. Y. A. Berry, of Edinburgh, suggest that it is a specialised mass of lymphoid tissue which the authors conceive may serve as a defensive mechanism against bacterial invasion in a portion of the bowel where, for anatomical and other reasons, there is a delay in the passage of the intestinal contents onwards, and special protection is therefore required against the absorption of bacterial products.

(3) This work is based on material collected in compilation of the Erasmus Wilson lectures, 1904. The author states that the main object of his lectures was to direct attention to the identity of the pathological changes concerned in the production of all acute perforative and gangrenous processes of the alimentary tract. He suggests that two extremes of tissue death or necrosis may be recognised, viz. that due to deprivation of blood and that caused by the action of micro-organisms. Between these two there are various grades and admixtures; the former is slow in action, the latter very rapid, and it is this which plays so important a part in abdominal necrosis. The work is practically a collection of notes, but is interesting reading.

(4) Prof. Wright has done well to collect into a single volume the various papers, with amplifications, he has from time to time contributed to various journals on the subject of anti-typhoid vaccination. The method of preparation of the vaccine, theoretical and practical considerations as to its use, and statistics of its value are all considered. With regard to the last named, it must be mentioned that some controversy has taken place in the medical Press as to

the validity of Prof. Wright's conclusions from the statistical evidence.

(5) This little book should be in the hands of every hygienist, and, since it deals largely with bovine tuberculosis, of every scientific stock owner. Behring is one of those who not only disbelieves the dictum of Koch of the essential distinction between human and bovine tuberculosis, but goes to the other extreme, and asserts that "the milk fed to infants is the chief cause of consumption," and he would insist on the pasteurisation of all milk. He asserts that pulmonary tuberculosis (phthisis or consumption of the lungs) is not an infection from inhaled tubercle bacilli. Besides pasteurisation, Behring also recommends the use of formalin as a preservative of milk, a procedure which will probably not commend itself to the authorities here, though there is a good deal to be said in its favour. Finally, he describes a method of vaccinating cattle against the tubercle bacillus by the aid of which he hopes eventually to stamp out bovine tuberculosis, and as a consequence human tuberculosis, a consummation devoutly to be hoped for.

R. T. H.

THE PIONEERS OF GEOLOGICAL THOUGHT.

Karl Ernst Adolf von Hoff, der Bahnbrecher moderner Geologie. By Dr. Otto Reich. Pp. xvi+144. (Leipzig: Veit and Co., 1905.) Price 4 marks.

THIS clearly written work, undertaken with a just enthusiasm, is a welcome and permanent contribution to the biography of scientific men. Von Hoff's position as an original thinker is at least equal to that of Lyell, though both writers, of course, found notable *Bahnbrecher* before them, in Hutton, Desmarest, and others. Karl von Zittel, in his "Geschichte der Geologie," held the balance very wisely between von Hoff and Lyell when he wrote,

"The third volume (of von Hoff's "Geschichte der . . . natürlichen Veränderungen der Erdoberfläche") is clearly influenced by Charles Lyell's first volume of the 'Principles of Geology,' which had appeared in the meantime. Von Hoff unreservedly adopts the point of view of the great British investigator; yet Lyell's views corresponded on the whole with what von Hoff had put forward ten years before as the result of his historical researches. The fact that von Hoff's meritorious work was not properly valued, and was put in the shade by Lyell's epoch-making book, which appeared almost simultaneously, is easily explained by the circumstance that the modest German man of science derived his material mainly from books, that his position did not allow him to examine in the field the questions which he discussed, and that he enriched science by no new facts; he faced his problem as a historian, and not as an observer."

Let us frankly admit, on the British side, that Lyell was not among the great original observers, and that his eminence rests on his brilliant perception of the meaning of correlated facts; yet his energy of movement and his frequent travels gave him an immense advantage over his contemporary. Dr. Reich shows us how von Hoff was occupied in many other affairs while preparing himself for his "Geschichte," a work of immense originality, and free indeed from the prejudices of his day.

In 1788 von Hoff entered the University of Jena, in his native region of Thüringia, and proceeded after two years to Göttingen. Here he found inspiration in the character and friendly help of Blumenbach; but his professional work lay in diplomacy, and in 1791 he was appointed Secretary of Legation under his own Government of Gotha, where his father was already a Privy Councillor. As in France, the scientific renaissance was accompanied by national movements that might well have extinguished private calm and study. Von Hoff was one of the delegates who, in 1806, pursued Napoleon's court from Berlin to Posen, and who secured the entry of Gotha into the saving grace of the Confederation of the Rhine. True to the interests of his State, he bore greetings to Jerome of Westphalia two years later, and helped to steer Gotha again into safe waters, this time under a German ægis, when Leipzig had seen the downfall of his alien suzerain. Yet, amid all the excitement of the times, when princes scampered rabbit-like from hole to hole, von Hoff founded a geological journal in 1801, met Werner in Gotha, and was struck by his mental limitations, spoke and corresponded heartily with Goethe, and explored the Thüringian Forest in a number of geological excursions. In the sanguinary year of 1806 he encountered Humboldt in Berlin, and the diplomat of Gotha was describing his native woodlands when the echoes of Friedland spread dismay through Germany.

In 1822 the first volume of his famous "Geschichte der durch Überlieferung nachgewiesenen natürlichen Veränderungen der Erdoberfläche" appeared from the house of Justus Perthes in Gotha; and Dr. Reich does well to press the claims of this work as the foremost and most rational attempt to free geologists from their popular catastrophic school. Dr. Reich (p. 107) quotes from Blumenbach to show that Hutton's views had spread to Germany in 1790, and that Voigt of Jena had already prepared the way by prior and independent conceptions of his own. Von Hoff surpassed Hutton in urging the power of existing causes working through long periods of time. This position had been reached by him as early as 1801 (p. 111), and his biographer is inclined on this account to accuse Lyell of overshadowing wilfully his predecessor. It is idle, however, to quote from the edition of the "Principles of Geology" issued in 1872 (p 131), in which numerous alterations and additions had led to much excision. Instead of the solitary quotation from von Hoff referred to by Dr. Reich in support of his contention, we find five references in the first edition of vol. i. (1830), and two more in the second edition of vol. ii. (1833). Five references, moreover, to von Hoff remain in the eighth edition of the "Principles," issued in one volume in 1850. Since Lyell in his first edition devoted nine pages to the views of Hutton, out of the seventy given to the history of geology, he can hardly be said, as Dr. Reich would have us believe, to have shown ingratitude to Hutton also.

In 1826, in a memorial notice of Blumenbach, von

Hoff proved how far he was prepared to go in accepting organic changes as the result of changes of the earth's surface. Side by side with a progressive development of the surface-features, he saw the necessity for a transformation in the nature of the organic world. The quotation given on p. 134 may not imply so much as Dr. Reich reads into it; but we are grateful to him for setting before us the absolute mental pre-eminence of von Hoff in the world of Continental geologists of his day, and the fact that, from one cause or another, no conception of his greatness and originality can be gained from the historical *résumé* of Lyell, with which all English readers are familiar. G. A. J. C.

MINE AIR.

The Investigation of Mine Air. By Sir C. Le Neve Foster, F.R.S., and Dr. J. S. Haldane, F.R.S. Pp. xii+191; illustrated. (London: Charles Griffin and Co., Ltd., 1905.) Price 6*s*. net.

SINCE the Hon. Robert Boyle published in 1671 his essays on "The Temperature of the Subterraneall Regions" and on "The Strange Subtilty of Effluviums," and Athanasius Kirscher devoted a chapter of his "Mundus Subterraneus" (1678) to the occurrence of inflammable gas in the Herrengrund copper mines, there has been a constant succession of memoirs dealing with the gases met with in mines. The latest addition to the series, by making accessible the results of German, French, and British investigations, should do much to add to the knowledge of the composition of mine gases and of their influence on human life. A large portion of the work was left in manuscript by Sir Clement Le Neve Foster at the time of his death, and such revision as was necessary has been undertaken by Dr. J. S. Haldane, who has added a section of great value, embodying a description of rapid methods of analysis that he himself has devised and an essay on the interpretation of mine-air analyses in the light of recent investigations.

The book is of a composite nature. The first section is a translation of the introductory treatise on mine-air analysis by Prof. O. Brunck, of the Freiberg School of Mines. The second section is a translation of a paper by Mr. Léon Poussigue on the measurement of air currents and fire damp at the fiery Ronchamp collieries, the deepest mines in France. The third and longest part contains a summary of Dr. Haldane's work on the examination of mine air. As an appendix is added a detailed account, from Sir Clement Le Neve Foster's reports to the Home Secretary, of the effects of carbonic oxide in connection with the Snaefell mine disaster in the Isle of Man in 1897. Sir Clement's exposure to carbonic oxide during the recovery of the bodies of the miners killed was the starting-point of the illness that ultimately proved fatal.

The methods of analysis for mine gases described by Prof. Brunck are simple, and in no respect less accurate than the most delicate methods of exact gas analysis. The fulness of the instructions and the simplicity of the methods should induce mining engineers to practise gas analysis and to regard it as an important guide to the safety of the workings placed under their charge.

Since November, 1891, a special department has been organised at the Ronchamp collieries for the purpose of determining the proportion of fire-damp in the workings. The Le Chatelier combustion apparatus is employed, and an assistant makes two hundred determinations a day.

In the third section the methods of determining oxygen, carbonic anhydride, nitrogen, and fire damp described by Dr. Haldane well fulfil the practical requirements of being very accurate and rapid. His method of obtaining and transporting samples of mine air in two-ounce stoppered bottles is trustworthy and much more convenient than Poussigue's method of using a 1½-litre bottle, or Winkler's method of using a 10-litre sheet-zinc vessel recommended by Brunck. One cannot help thinking that in the latter case prolonged storage in a zinc vessel would have an effect on the composition of the gas. In Dr. Haldane's dry bottles no sensible alteration of the contained sample occurs within a fortnight or more. His method of gas analysis is similar to that originally described by him in the *Journal of Physiology* in 1898; and he now describes for the first time a portable apparatus, enclosed in a wooden case measuring 7 by 12 by 2½ inches and weighing 5½lb., by means of which accurate determinations may be made, on the spot underground, of various impurities in the air. He also describes a convenient method of determining the quantity of stone-dust in the air of working places in metalliferous mines. The disastrous effects produced by the habitual inhalation of air containing stone-dust are now generally recognised. The air of an "end" or "rise" just after blasting contains large quantities of dust, and the men ought not to return until there is less than 1 milligram in 10 litres of air. The average air of a "stope" where men are working should not yield any weighable dust in that quantity of air.

Obviously a complete analysis of mine air is useless unless the significance of the results is understood. The chapter on the interpretation of mine-air analyses is consequently of far-reaching importance. Dr. Haldane advocates the use of the convenient term "black damp" for the nitrogen and carbonic anhydride. It is the gaseous residue resulting from the slow oxidising action of air on oxidisable substances in a mine. It is very commonly confused with carbonic anhydride, but it really consists chiefly of nitrogen. Black-damp, which was nothing but pure nitrogen, was described by Mr. H. A. Lee (*Proc. Colorado Scientific Society*, vol. vii., p. 163, 1904) as occurring in a metalliferous mine in Colorado. A useful section on the effects of air impurities on men concludes part iii. Much of the information in this part has already been published by Dr. Haldane in Home Office reports and in papers read before the Institution of Mining Engineers; but an authoritative summary of the results arrived at is a welcome addition to technical literature.

The book, which was originally intended for Le Neve Foster's students at the Royal School of Mines, should prove invaluable, not only to mining engineers at collieries, but also to those engaged in metalliferous mines.

B. H. B.

AN INDIAN GARDEN.

An Indian Garden. By Mrs. Henry Cooper Eggar. Pp. viii+181; illustrated. (London: John Murray, 1904.) Price 7*s*. 6*d*. net.

AN unpretentious little book, written in an easy vein, printed on very light paper and in the best of type, "An Indian Garden" might well be suited to while away pleasantly an idle hour. There is so much freshness about the book, so much enthusiasm for the author's garden, such a lovable unconsciousness of the inward triviality of the hundred and one little incidents, servant, cobra, and dog stories and harmless gossip woven into this tale of amateur gardening, that one would fain make the personal acquaintance of the writer. As we read on, our interest centres more and more in the healthy, vigorous, and amiable personality that sways this old Indian Garden of 5½ acres, whilst the garden itself, with its old trees, its amaryllis and caladium beds, its fernery, its obstreperous lawn of "Dooba" grass (*Cynodon Dactylon*), and its general propensity to run back to jungle, becomes so much background.

In those circumstances one forgets to look out for any systematic information on the conditions of gardening in India, nor is there any room for criticising seriously the author's botany. One does not stop, for instance, to ponder over the curious "almond tree" (p. 43) with the convolute embryo, or mind that the lycopodium (p. 50) "that turns a beautiful electric blue in the shade" is in reality a Selaginella (*S. uncinata*), or that the deodars (p. 141) which ripen their berries in July are evidently the debdars (*Polyalthia longifolia*) mentioned repeatedly in the earlier pages. It must all be beautiful, and one longs to see it.

We are not told where the garden is. Its whereabouts, like other things in the book, are hidden under a delightful incognito. It is just a few feet above the sea in a vast plain "with never a rise, sufficient to be called a hill anywhere near for 100 miles." It may be, and very likely it is, in Bengal, as the locality from which the preface is dated and other indications suggest; but that, again, matters very little. It is in keeping with the light, playful humour which pervades the whole book. Still, it would be unfair to pass over the fact that there are passages in it which for keenness of observation, terseness and descriptive power, rise high above the average level of the book. Thus on p. 41, "I like the Casuarinas, though they are bad gardeners, and suck up all the moisture in the earth for some long distance round their roots, so that nothing can possibly live near them; sometimes in the early morning they weep it all back copiously like rain"; or on p. 145, "If one wanted to photograph the movements of an opening blossom, one should select the *Crinum augustum*. It is a noble plant, this lily; about 4 feet high, with scented flowers, numbering 22 in a bunch at the end of a long stalk as thick as a ruler. I passed by one just after a shower of rain this evening, and noticed that four or five of the 4 inch long, pink-striped buds were just ready to open. I came by again shortly after, and lo! and behold! they *were* open, quite wide open, too. In my next turn, 20 minutes after, the long petals had entirely curled themselves backwards like rams' horns. One could see them all a-quiver with the intensity of the movement still. In one hour the points of those petals must have described an arc of 8 or 9 inches or more!"

There is a dainty coloured frontispiece representing a branch of an Antigonon (evidently *A. leptopus*)—though it is difficult to see why a representative of an exclusively American genus should usher in "An Indian Garden"—and eighteen illustrations, photographic prints, some of them veritable gems for their general beauty and exquisite clearness.

OTTO STAPF.

OUR BOOK SHELF.

Animals I Have Known. By A. H. Beavan. Pp. 304; illustrated. (London: T. Fisher Unwin, 1905.) Price 5*s*.

IF the present rate of issue be much longer maintained, popular books on mammals (or "animals," as they are still called by the man in the street) will soon begin to rival in number those devoted to birds. In the volume before us the author, without having anything specially new to communicate, discourses pleasantly enough on the mammals (both wild and domesticated) of our own islands, as well as on those of two other countries, namely, Australia and South America, with which he is personally familiar. His anecdotes and descriptions are emphasised by the numerous reproductions from photographs with which the work is illustrated. Most of these are first rate, the one of the thylacine, or Tasmanian wolf, showing to perfection that gradual merging of the tail in the body to which the author specially alludes, and which so markedly distinguishes many of the lower mammals from their more specialised relatives.

Unfortunately, the text is marred by a number of more or less inexcusable blunders and errors, which cannot but deceive the class of readers for whom the book is intended. On the very first page we are told, for instance, that there lived in Britain during the mammoth period "tapir-like three-hoofed creatures with long snouts." This can evidently be nothing else than the Oligocene palæotherium, an animal to which reference is again made on p. 279, where the author observes that he has momentarily forgotten its name—a nice admission to make in print! A similar "muddle" in regard to palæontological chronology is made on p 16, where we find opossums included among the British Pleistocene fauna. Even more serious is the deliberate statement on p. 222 that the duckbill, or platypus, is the only known oviparous animal—more especially in view of certain doubts that have been expressed of late years as to whether this species does actually lay eggs. Again, on p. 291 we are told that all South American monkeys are furnished with prehensile tails, while ten pages later we are informed that the vampire bat taps the blood of its victims with its canine (instead of incisor) teeth. Moreover, in the plate on p. 299 the author figures as that of the true blood-sucking vampire the head of a javelin-bat (Phyllostoma) or a nearly allied species. Possibly the latter species may occasionally suck blood, but it is not the vampire *par excellence*. In the figures of a bat on p. 91, which

may be presumed to be intended for the pipistrelle, the tail is entirely omitted, so that there is nothing to support the median extension of the interfemoral membrane! The following remarkable sentence (p. 202), we are glad to acknowledge, is not typical of the author's style:—"The koala's habits are sluggish, and though able to climb well, moves about the trees in a most deliberate manner." R. L.

Queen-Rearing in England, and Notes on a Scent-producing Organ in the Abdomen of the Worker-Bee, the Honey-Bees of India, and Enemies of the Bee in South Africa. By F. W. L. Sladen. (Houlston and Sons, 1905.)

THE scope of this little work by a practical bee-keeper is sufficiently indicated by its title, and the bulk of its contents has already appeared in the British *Bee Journal* and the *Entomologist's Monthly Magazine*. There is a coloured frontispiece representing the queen and worker of the Golden Italian bee, and there are numerous text-illustrations of no remarkable excellence After a chapter on queen-rearing in nature, several chapters are devoted to the best artificial means of securing a supply of queens for multiplying or improving bee-colonies; and a brief account is given of different races called the Italian (or Ligurian) Bee, the Golden Italian Bee, and Carniolan Bee, and the Cyprian Bee. In a later chapter Mr. Sladen remarks that when vibrating their wings, and especially when swarming, bees produce a peculiar tune which has been supposed to attract their comrades; but the author thinks the attraction is at least partly due to a powerful scent emitted when a membrane situated between the fifth and sixth dorsal segments of the abdomen is exposed. This is fully described and figured. Short chapters on the honey bees of India (*Apis dorsata, florea,* and *indica*), and on enemies of bees in South Africa; "Bee Pirates" (sandwasps belonging to the genera Palarus and Philanthus), a Tachinide parasite in the abdomen; and a species of Chelifer conclude the work.

Physical Experiments. By N. R. Carmichael. Pp. xi+127; with diagrams. (Kingston, Ontario: R. Uglow and Co., 1904.)

ANYONE drawing up an elementary course of mechanical and physical experiments, and wishing for a manual to accompany it so as to make the preparation of a special volume unnecessary, could hardly do better than adapt his course to the manual before us. It contains just the short description which would otherwise be produced by some copying process for distribution to a class, or, failing this, would probably be written on a blackboard. That is to say, there is just enough description to indicate to a pupil what he is expected to do, and which would be copied by him into his notebook. A teacher will require to amplify the book verbally, either in the course of a short demonstration at the beginning of the class, or, if his lectures and the practical work run together very well, this might sometimes be done in the course of the lectures. The aim that Mr. Carmichael has had before him has been to state concisely the nature of the quantity to be measured in each experiment and the theory underlying the method suggested. Descriptions of instruments are entirely omitted, as the students are expected to have the apparatus given them by an instructor.

With regard to the selection of experiments, the object has been to give students who have but a limited time for laboratory work a practical acquaintance with as many physical quantities as possible. The fact that the author is a teacher in a school of mining is a guarantee that the technical student is intended to be served; but it is the more academic, but equally necessary, side of his training that is here catered for.

An Introduction to Elementary Statics (Treated Graphically). By R. Nettell. Pp. 64. (London: Edward Arnold, 1905.) Price 2s.

THIS book consists of a set of graduated exercises in graphical statics. The first seventy, about half the total number, are restricted to problems on the equilibrium of three forces at a point, and are intended to be worked by means of the parallelogram of forces. In succeeding problems the triangle of forces and the polygon of forces are introduced. The principle of moments is also employed. A few examples are given of the determination of the centre of gravity of simple plane figures, and in the final examples the subject is carried as far as the equilibrium of four non-concurrent forces in one plane. The link polygon is not used, so that parallel forces are scarcely referred to. It will be seen how extremely limited is the ground covered by this book. The constructions are not founded on or verified by experimental work of any kind. No vectors other than force vectors are introduced. Trigonometrical calculations, even of the simplest kind, are rigidly excluded. The book is intended to be used by classes of young boys, but its scheme does not harmonise with the ideas now prevalent as to the way in which elementary mathematics should be taught to youths.

The Elements of the Differential and Integral Calculus. By D. F. Campbell. Pp. x+364. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1904.) Price 7s. 6d.

THIS book seems well adapted to serve as a text-book for a first course in the differential and integral calculus. Fourteen chapters deal with the differential calculus and its applications to maxima and minima values, expansions in series, and the geometry of plane curves. The fundamental ideas of integration are very fully explained, the second fourteen chapters being devoted to the integral calculus and its application to finding plane areas, lengths of curves, areas of surfaces, and volumes. In a short chapter dealing with approximate integration, the first and second elliptic integrals are introduced, and three-figure tables for $F(k, \phi)$ and $E(k, \phi)$ are given. A few elementary chapters on mechanics have been introduced, so that the student may be able to view from the mechanical, rather than from the purely mathematical, side the principles of attraction, centre of gravity, and moment of inertia. Numerous exercises, with answers, are given with each chapter. The diagrams are clear, and the type is excellent.

Völkerpsychologie. By Wilhelm Wundt. Vol. i. Die Sprache. Second revised edition. 2 parts. Pp. xv+667, x+673. (Leipzig: Wilhelm Engelmann; London: Williams and Norgate, 1904.) Price 14s. net and 15s. net; bound, 17s. net and 18s. net.

THE first volume of this monumental work has reached a second edition, some sixty or seventy pages bulkier than its predecessor (reviewed in NATURE on January 16, 1902). The most important changes affect the fourth chapter, *Der Lautwandel*, the sixth, *Die Wortformen*, and some parts of the theory of the sentence. A first edition of the other volumes, dealing with myth and custom, has not yet appeared; it is to be hoped that it will not be unduly delayed by the necessity of revising the present instalment, and that in any parts still to appear the wood will be less closely concealed by the trees.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

History of a White Rhinoceros Skull.

IN his interesting "Natural History Essays," in which occurs the description of the white rhinoceros, Mr. Graham Renshaw makes the following reference to the first skull of this animal which was brought to England:—

"It would be interesting to know if the white rhinoceros head brought to England by the Rev. John Campbell, about 1815, is still in existence. It appears to have been preserved as late as 1867 in the Museum of the London Missionary Society at Finsbury, but there seems to be no mention of it during recent years in zoological literature. In a figure now before me the artist has absurdly furnished the open jaws with an imaginary series of perfectly regular pseudomolar teeth: the square mouth has been distorted to resemble the prehensile lip of the black species, though the slit-like nostrils, position of the eye and semi-tubular ears are delineated with fair correctness. The anterior horn of this individual is said to have been 3 ft. long: and, *as figured*, from its slender-

FIG. 1.—Skull of the White Rhinoceros in the American Museum of Natural History.

ness recalls Col. Hamilton Smith's description of the mysterious horn, brought from Africa, from which he sought to deduce the existence of a true unicorn in the interior of that Continent" (p. 146).

In 1902 this very skull was purchased from Mr. Cecil Graham for the American Museum of Natural History by Mr. J. Pierpont Morgan. Mr. Graham has made a large and valuable collection of rhinoceros horn weapons, clubs, knob-kerries, and battle axes, and in course of correspondence he wrote of his discovery of the skull as follows:—"There is no record as to how or when the specimen was first brought to England. I found it by chance a few years ago in the City, lying neglected and dirty on the floor of a back room of the London Missionary Society. No doubt it was presented by a missionary before 1821. I especially value the letter dated 1821."

The letter referred to by Mr. Graham is from William Cooke, of the Royal College of Surgeons. It is dated November 20, 1821, and addressed to William Alers Hankey, Esq., Fenchurch Street. It reads as follows:—

"My dear Sir,

"The head in the missionary museum supposed to be the head of the unicorn, appears to belong to a species of Rhinoceros previously unknown in this country, at least, there is no such specimen in the Hunterian Museum which may be regarded as the National Depository for comparative anatomy. In that grand collection there are heads which nearly resemble it, but there are points in which the diversity of conformation indicates a decided *specific* difference.

"Permit me to suggest to you, and through you to the Directors of the Missionary Society, that a rare specimen of that nature is entitled to a place where it can be more justly appreciated than it ever will be in their collection. I need not suggest to you the advantages which result from a concentration of the different productions of nature—from bringing under one view the genera and species of the various natural sciences—especially when they are not only rendered available for minute distinction, but by a liberal policy are accessible to men of science from all parts of the world. I can have no selfish motive in suggesting that the head possessed by the Missionary Society would become much more an object of interest if deposited in the Hunterian Museum, than it ever will be should it remain in the Old Ivry. If deposited at the College of Surgeons it will not only fall under the notice of Naturalists from all quarters, but it will likewise be a subject of reference in the lectures on comparative anatomy annually delivered at that Institution.

"The Missionary directors unquestionably will consider the advantages which may result to their own Society, as well as the promulgation of scientific knowledge; and if I might presume to express an opinion on this subject, it would be in favour of the head being presented to the College. It would there be preserved as a testimony of praiseworthy liberality—it would soften prejudice, where perhaps there is a deep-rooted antipathy to religion, but where conciliation is of great importance; and if it remain in its present situation for a few years it will be liable to destruction, or to essential injury at least.

"If you have never seen the Museum of the College of Surgeons it would afford me great pleasure to accompany you thither any Friday.

"I feel assured, my dear Sir, that you will excuse the liberty I have taken in addressing you on this topic;—and believe me to be

"Yours most obediently and
"respectfully
"(signed) WILLIAM COOKE."

In spite of this appeal, the skull evidently remained in the possession of the Missionary Society until Mr. Graham rescued it from oblivion. Although the occipital portion has been sawn off, it is a remarkably fine specimen, as shown by the accompanying photograph. The nasal horn is firmly attached to the skull; the frontal horn is detachable, but readily fits in place. The principal measurements are as follows:—

Total length of skull, along top ..	778 mm.	$=30\frac{5}{8}$ inches
Length of grinding series	287 ,,	$=11\frac{1}{4}$,,
,, frontal horn	280 ,,	=11 ,,
,, nasal horn	890 ,,	=35 ,,

(Measured on a straight line.)

The skull is now exhibited with two war clubs manufactured from the nasal frontal horns of the white rhinoceros, with a skull of the related woolly rhinoceros from Siberia, presented by the Moscow Museum, through Madame Pavloff, also with a skull of the *Rhinoceros pachygnathus*, a related or ancestral form, from Pikermi, presented by the Munich Museum through Prof. von Zittel.

HENRY FAIRFIELD OSBORN.

American Museum of Natural History, New York,
April 24.

Fictitious Problems in Mathematics.

YOUR reviewer gives a new definition of "a perfectly rough body" (NATURE, June 1), which he says is that of the mathematician. The definition appears to me to contradict what he has elsewhere said. But I need not enlarge on this point, for his criticism of a problem should be tried, not by his definition, but by that given in the book in which the problem occurs.

The reviewer accuses Cambridge examiners "of endowing bodies with the most inconsistent properties in the matter of perfect roughness and perfect smoothness"

(NATURE, April 27). He adds, as an explanation, that "the average college don" forgets an elementary law of friction. But the proper inference is that the definition of the reviewer is different from that in common use. It is difficult to believe in this general forgetfulness.

The various letters sent to NATURE sufficiently show what meaning is usually attached to the words.

June 3. E. J. ROUTH.

WHY JAPAN IS VICTORIOUS.

TEN years ago, after the conclusion of the war between Japan and China, it was remarked that the sound of the Japanese cannon at the mouth of the Yalu River awoke the nations of the world to the fact that a new Power had arisen in the Far East which in future would require to be taken into account when any political problems arose. It is, of course, recognised by all who know modern Japan that the most important factor in the making of new Japan has been the applications of science to the arts both of peace and war. Without these, even the spirit of the samurai would have been as powerless before the attacks of Western Powers armed with all the latest warlike appliances, as were the dervishes at the battle of Omdurman. Spectators speak with admiration of the bravery of these men and with pity that their lives were thrown away in a vain resistance. Without the help of science and its applications it is very certain that, before this time, Japan would have been overrun by a European Power after immense slaughter, for the last man would have died, fighting with his primitive weapons, rather than recognise a foreign domination.

A careful study of the evolution of modern Japan shows plans founded on enlightened principles and carried out in every detail. In fact, one of the secrets of the success of the Japanese in the present war is that nothing is left to chance; every detail is worked out and carefully provided for. They soon recognised that their national ideals would never be realised without a system of education, complete in every department, which would supply the men who were required to guide the nation under the new conditions which had emerged. Elementary education was organised all over the country, secondary education in central districts, and technical education wherever it seemed to be required. Above all, there are two national universities which in equipment and quality of work done will bear favourable comparison with similar institutions in any other country in the world.

The educational work of the country was directed not simply to personal or sectional purposes, as is unfortunately too often the case in the West; it was also consciously directed to the attainment of great national ends. Every department of the national life was organised in a rational manner, and, therefore, on scientific principles. In many departments there is still much to be done, but past achievements promise well for the future.

Special attention has been paid by the Government to the applications of science. Without the railways, the telegraphs and telephones, the dockyards, the shipbuilding yards, the mines, and the engineering establishments, the existence of the army and navy would have been impossible; at least, if they did exist they would have been nearly powerless. The operations of the present war with Russia have clearly demonstrated the importance of the introduction of the scientific spirit into all the national activities. The railways which have been built in Japan have been fully utilised to convey men and materials and the ships to transport them oversea. The telegraphs have been used to communicate instructions and to keep the authorities informed regarding movements and requirements. The dockyards and shipbuilding yards have been ready to undertake repairs, and the arsenals and machine shops to turn out war material of all kinds, as well as appliances which aid operations in the field. Light railways have been laid down on the way to battlefields, and wireless telegraphy and telephones to convey instructions to the soldiers; in short, all the latest applications of mechanical, electrical, and chemical science have been freely and intelligently used.

The Japanese have not only modified Western appliances to suit their conditions, but they have also made numerous distinct advances. The ships of their navy are probably the best illustration of the Japanese method of procedure. In naval matters they accepted all the guidance the Western world could give them, but at the same time they struck out a line of their own, and the fleet which they have created is unique in the character of its units. British designs have in many respects been improved upon, with the result that they have obtained in their latest ships many features which have won the admiration of the world. The training of Japanese naval officers is very complete in every way, and in some respects offers an example to the British authorities, and the men are devoted to their profession. Japan now sends her picked men to Europe to complete their studies, so that in every department of national life they are kept up with the latest developments. The siege of Port Arthur, the battle of Mukden and the other battles in Manchuria, and the exploits of the Japanese Navy prove most distinctly that they have profited by their experience.

The intense loyalty of the Japanese, which compels them to make any sacrifice, combined with their great intellectual ability, enables them to take full advantage of the modern science and organisation necessary for the attainment of the objects of their ambition. Their great power of foresight prepares them for all their enterprises, both of peace and war, with exact and scientific precision. While they are permeated by Eastern ideas they have been able to appropriate much that is best in Western thought, and thus they unite many of the best qualities of the East and the West.

The lesson which our educationists and statesmen have to learn from Japan is that the life of a modern nation requires to be organised on scientific lines in all its departments, and that it must not be directed chiefly to personal ends, the attainment of which may, to a large extent, intensify many of our problems, but that it be consciously used for the promotion of national welfare.

But though the lesson is plain enough, apparently it is not understood by those whose business it is to promote national welfare by guidance or counsel. With one consent our newspapers have attributed Japanese success to all reasons except the right one; and, instead of opening the eyes of the nation to our pressing needs and deficiencies, they have been blind leaders of the blind. Our public men and our Press will not see that scientific education has brought Japan to her present position in thirty years, and that, if we choose to educate ourselves, we may arrive at the Japanese standard of national efficiency. The progress which this country has made since the Middle Ages is due to the discoveries of men of science, whose work has been done in spite of discouragement or national indifference. In the new atmosphere of Japan a scientific spirit prevails, which encourages development, with the result that the nation has in a generation arrived at a position which has taken us centuries to reach. It is not compli-

mentary to us as a nation to say that our patriotism, fear of death, or nerves compare unfavourably with similar attributes of the Japanese; and, after all, this is a matter of opinion. The fact to face is the transformation which science has effected in Japan, and the sooner our statesmen are educated to see it, the more promising will be the outlook for the British nation.

SOLAR CHANGES AND WEATHER.

DURING the last few years more than usual attention has been paid to the question of the relationship between sun-spots or prominences and "weather," and to the possibility of being able in the near future to forecast the characters of approaching seasons. Quite recently in this Journal (vol. lxxi. p. 493, March 23) we referred briefly to a pamphlet published by the United States Department of Agriculture, Weather Bureau, summing up the general state of the problem of long-range weather forecasting. In this it was stated that advances in the period and accuracy of weather forecasts depend upon a more exact study and understanding of atmospheric pressure over large areas, and a determination of the influences, probably solar, that are responsible for normal and abnormal distributions of atmospheric pressure over the earth's surface.

In the April number of the *Popular Science Monthly* the question of the relationship between sun-spots and weather is summarised in an article by Prof. Ernest W. Brown, of Haverford College. In this we have an interesting account of the problems waiting solution, and he brings together in a very clear manner a general survey of the relationship, or rather non-relationship, as he concludes to be the case. Thus he says, "it is highly probable that the direct effect of the spotted area is unimportant compared with the effects produced in our atmosphere by other causes." In his final summing up he remarks that his opinion is expressed by Prof. Cleveland Abbe, who stated that:—"The key to the weather problem is not to be found in the sun or indeed in any external influence, but that the solution is to be worked out by the conditions which hold in the atmosphere itself—conditions which can only be discovered by a thorough examination of the internal laws of motion, quite apart from any external forces which may modify the results."

In referring to the difficulties which are met with in examining the meteorological conditions on the earth's surface, Prof. Brown points out that observations made "at one place should be kept separate from those at other places, for it is theoretically possible and even probable that a maximum at one place of observation may occur at the same time as a minimum at another place. For example, the yearly averages might show that a maximum rainfall in one place always occurred with a minimum rainfall in another and *vice versâ*."

In the last quotation Prof. Brown makes a suggestive remark which recent work has shown to be an actual meteorological fact; it has already been completely established for pressure, and must therefore hold good as regards rainfall, since the latter depends on the former.

In the case of these variations of barometric pressure it has been shown, and referred to at some length in this Journal (vol. lxx. p. 177, June, 1904), that there exists a barometric see-saw on a large scale the presence of which has been amply corroborated by Prof. Bigelow, of the United States Weather Bureau. There seems little doubt that it is this pressure change that will eventually prove the "key" to the situation, and its solar origin has already been suggested in the changes in the frequency of prominences, which are, after all, allied to sun-spots.

Up to the present time those who have been attempting to explain variations of weather on the supposition of solar changes have been looking for the effect of solar action as either increasing or decreasing simultaneously the rainfall over the whole earth. The consequence has been that a study of a great number of statistics has shown that in some regions the rainfall varies directly with the number of sun-spots, and that in others the variation is inverse, while, again, in other parts there seems to be no apparent relation at all. In fact, these deductions, though quite correct, have led to the conclusion that the solar connection is of a very questionable character, as it was considered impossible for such opposite results as the first two just named to have their origin in one solar change.

It is the employment of this incorrect working hypothesis that has probably retarded the progress of the study of the connection between solar and meteorological changes.

The now recognised existence of this barometric see-saw shows that the sun's action must have a *double* effect on our atmosphere, and this of an opposite nature. Such a result is quite natural, and it is curious that use has not been made of it before.

When it be considered that the amount of air in our atmosphere is a constant quantity, a greater piling up of it on one side of the earth must necessarily mean a diminution in the antipodal regions. If greater heating power of the sun takes place, then the atmosphere must also be heated to a greater extent, and consequently more intense up-currents of warm air are formed, resulting in more pronounced low-pressure areas. There must, however, be a compensating effect somewhere, and this is found on the opposite side of the earth when the previously heated air arrives, descends, and creates an area of excess pressure.

This backward and forward transference of air becomes, therefore, of great importance in studying the weather changes in any one region, because the rainfall phenomena are so closely related to the pressure changes.

Away from the middle portions of those two large areas which behave in this see-saw manner, the variations of pressure should, and actually do, have a different periodic nature. It is of extreme importance, therefore, when trying to trace the sun's action on our atmosphere, to separate the regions over which the variations may be truly solar from those which exhibit variations modified by the mechanism of the atmosphere itself.

There is therefore no reason why we should take a pessimistic view of the attempts made to solve this fascinating riddle of the relationship between changes of solar activity and the vagaries of the weather. An enormous amount of accumulated material is ready for discussion, and efforts should be made to secure the continuity of these observations and at the same time to coordinate the data along lines most suitable for this particular research.

WILLIAM J. S. LOCKYER.

THE SURVEY OF INDIA.[1]

THE extracts from the narrative reports of the Survey of India for the years 1902–3 are contained in a thin and attenuated volume of some eighty pages, which, as compared with previous reports, represents the effects of Indian financial economy applied to one of its most interesting departments.

[1] "Extracts from the Narrative Reports of the Survey of India for the Season 1902–3." (Calcutta: Government Printing Office, 1905.) Price 2s. 3d.

A committee is now sitting somewhere in India to decide on the best method of increasing the efficiency of the Indian survey department from the point of view (amongst others) of the English expert. It may be doubted whether the Indian surveyor has much to learn from the English expert, excepting in the science of map reproduction; but it may be that the Indian financier will learn therefrom that the way to improve and develop a department is not to starve it under the pressure of each successive spasm of financial depression, but to give consistent support to its work in the field and encourage the publication of such results as are of world-wide interest. Compare this half-starved production with the survey reports of North America, of Canada, of any Continental country, or even with the intermittent publications of South America, and it would really appear as if India offered no field for scientific research that was worth a descriptive record. The report is unworthy of the Government of India.

There is apparently but one triangulation party now existing in India which works on geodetic principles, and this is gradually pushing its network of triangles through Burma, giving a good basis for two topographical surveys to extend their minor triangulations and lay out a framework for detailed mapping. Only these two topographical parties figure in the report, and the narrative of their progress is confined to the dullest of all dull statistics. Yet one of them is working in the Shan States on the Chinese frontier, where, if anywhere in the eastern world, there must be a most delightful field for new experiences and original observation.

Of geographical exploration on or beyond the Indian frontier, or of scientific investigations in the Himalayas, there is not a word in the report; nor, for that matter, is there the faintest reference to the solid work of the revenue and forest surveys which are spread in more prosaic form over half the continent. Possibly there may be much of really stirring narrative rendered by the officers concerned in trans-frontier work to which it is not deemed well to make any allusion. This is comprehensible on the grounds of political prudence, but the worst feature of this form of suppression is that it is apt to be permanent. A report once pigeon-holed in an Indian office might almost as well be solemnly committed to the earth with a spade. The man who wrote it, and who knew what he wrote about, leaves India at the mature age of fifty-five, and thereafter has nothing further to say to it. His opinion is never consulted, and it becomes merely a matter of academic interest to him to watch a new generation of frontier administrators floundering along by the light of experiences gained, let us say, in South Africa or in Egypt. He faintly wonders what has become of all the detailed information of the Indian frontier gathered in his time at the cost of so much labour and expense.

There is, however, doubtless much to be learnt from the series of tidal, levelling, and magnetic tables which take up nearly fifty of the eighty pages of the report, although it is not easy to recognise their claim to be considered narrative. Presumably these tables are published for the benefit of the comparatively few men of science who are interested in these special classes of investigation, but they hardly seem to justify the title of the report, and should certainly be preserved (as they probably are) in other forms more readily accessible for purposes of reference.

There is an account of a local survey (including levelling operations) which was undertaken for the benefit of the salt revenue department in order to ascertain the source of the Sambhar Salt Lake water supply. The result of the investigation would have been interesting had it been stated. The lake was surveyed thirty-eight years ago, and the source of supply carefully examined then. Probably the report was pigeon-holed.

It would be pleasant to congratulate Colonel Longe on the success of his first administrative report as Surveyor-General of India, but, as a matter of fact, it is obvious that hardly even the skirts of narrative have been touched so far as the Survey of India is concerned, and we can only hope that there may be another and a more comprehensive report issued hereafter in some other form.

T. H. H.

NOTES.

It cannot be too often emphasised that Japan owes its triumphs chiefly to the adoption of the scientific spirit as the essential principle of national progress. The State that accepts this axiom of practical politics secures for itself a place among leading nations; while, on the other hand, the country that gives little or no encouragement to science must fall behind in the future. The Paris correspondent of the *Times* states that this view is taken by M. Ludovic Naudeau, who, in the course of a telegram from Tokio on the causes of the Russian defeat, remarks:—"It is now idle to attempt to hide the fact that never was the Russian lack of science, of the modern spirit, or, to speak frankly, of intelligence—never was the absence of training and of enthusiasm which retards the efforts of the whole Empire displayed in a more melancholy fashion than in the Sea of Japan. All the Russian inferiority is in the intellectual sphere." We understand that even in the midst of the war, the subject of education is being keenly discussed in Japan. In our own country it is necessary to urge that satisfactory provision for the future can only be made by taking a wide view of scientific education, and by insisting that all who have the affairs of State under their control should possess such a knowledge of the methods of science as will enable them to understand that the most potent factors of success in the arts of peace or of war are scientific education and research.

Under the name of the Potentia Organisation, an international association has been formed with the object of establishing among nations a mutual relationship and cooperation for the diffusion of accurate information and unbiased opinion concerning international events and movements, and to combat narrow, prejudiced, and often interested views and news that contribute so much to international mistrust and misunderstanding. It is proposed to publish throughout the world, through the medium of newspapers and reviews, statements of simple fact and expressions of opinion by eminent public men of all nations on all important political, social, philosophical, economic, scientific, and artistic questions, to present the sincere views of experts on all current international events, and to refute false or biased news and views calculated to spread error and to endanger the peace and progress of the world. A cosmopolitan alliance of this kind should meet with many adherents in the world of science, in which the sole aims are the discovery of truth and the extension of natural knowledge. We trust that the organisation will do something to show that scientific culture is at the foundation of all national progress.

Mr. Stanley Gardiner, leader of the Sladen Trust Expedition for the exploration of the Indian Ocean between Ceylon and the Seychelles in H.M.S. *Sealark*, has sent Prof. Herdman a letter from Colombo (May 7) in which he gives the following provisional programme:—Leave

Colombo May 8, arrive Chagos Archipelago about May 20, and work there until about July 15; arrive Mauritius about August 1, and stay until about August 15; arrive Seychelles about September 8, leave about September 15, and return there on October 15 after visiting the various Amirante Islands. A second steam-launch has been acquired, and Mr. Stanley Gardiner considers that he is now fully equipped for work. The expedition will probably be next heard of from Peros Banhos, which ought to be reached early in June.

A REUTER telegram of June 1 states that a severe earthquake shock was felt in the morning of that day throughout the whole of Montenegro.

WE regret to see the announcement of the death of Mrs. Emma Hubbard, who at various times contributed to our correspondence columns interesting observations on natural history, more particularly on the subject of birds and their ways. Mrs. Hubbard also did useful service to science by indexing scientific works, among them being Sir Michael Foster's "Physiology" and her brother's "Ancient Stone Implements."

THE first International Congress of Anatomists will be held at Geneva, Switzerland, on August 7 to 10. The following national societies are to participate in this congress:—the Anatomical Society of Great Britain, the Anatomische Gesellschaft, the Association des Anatomistes, the Association of American Anatomists, and the Unione Zoologica Italiana. The organisation of the congress has been entrusted to a committee representing these societies, and consisting of Profs. Minot, Nicolas, Romiti, Symington, and Waldeyer. The presidents thus far named are Prof. Sabatier, of Montpellier; Prof. Romiti, of Pisa; and Prof. Minot, of Harvard. The congress owes its successful initiation largely to Prof. Nicolas, of the University of Nancy, to whom inquiries may be addressed.

ON June 1 the Prince of Wales paid a private visit to the Cotton Exhibition at the Imperial Institute, which is being held by the Board of Trade in conjunction with the British Cotton-growing Association. The exhibition, which has been arranged by the scientific staff of the Imperial Institute under the direction of Prof. Wyndham Dunstan, F.R.S., in consultation with Sir Alfred Bateman and Sir Cecil Clementi-Smith, the managing committee of the institute, is intended to show not only the progress of cotton cultivation on British soil, but also to indicate the stages in the conversion of the raw material into the manufactured fabric. Bulk samples of commercial cottons grown in different parts of the Empire are supplemented with small specimens arranged to show the length of staple, and are accompanied by photographs of cotton fields, ginneries, &c., and statistical diagrams and maps. The British Cotton-growing Association, in addition to their raw cottons, exhibit a unique collection of native textiles. The machinery section includes models of Arkwright's machines, a power-loom in operation, and several testing machines. Manufacturing processes are illustrated by specimens and explained by means of diagrams, and samples of goods produced by special processes, including the making of "selvyt," are on view.

THE weather report issued by the Meteorological Office for the week ended on June 3 showed that the rainfall since the beginning of the year had only exceeded the average in the north of Scotland (excess 5·4 inches) and in the north of Ireland (excess 0·8 inch). The greatest deficiency was in north-east England (3·2 inches) and in the midland and southern counties (2 to 2·6 inches). The heavy downpours in the early part of this week will have contributed something towards making up the deficiency, especially in the eastern and southern parts of the kingdom. The *Daily Weather Report* of Monday last showed a great change in the distribution of barometric pressure, there being a steady increase over the northern and north-western districts, and a shallow depression having formed over France. During the twenty-four hours ending at 8h. a.m. on Tuesday, the rainfall was continuous and heavy over the south and south-east of England, amounting to nearly 2 inches at Dungeness, 1·5 inches at Clacton-on-Sea, and to an inch in London, the rain still continuing, practically without cessation, during the whole of Tuesday. The heaviest falls reported for the twenty-four hours ending 8h. a.m. on Wednesday were 0.57 inch in London and nearly half an inch at Oxford and Bath.

THE *Engineering and Mining Journal* records that payable ore has been reached at the New Chum Railway Mine, at Bendigo, Victoria, at a depth of 4262 feet. This is the greatest depth at which gold mining has been carried on. It has, however, been exceeded at the Lake Superior copper mines.

THE plans have been completed for the fifteen-story building, to cost 195,000*l.*, which Mr. Andrew Carnegie is to present to the engineering societies of New York. Adjoining it in the rear will be a thirteen-story house for the Engineers' Club, which is to cost an additional 75,000*l.*, and is also part of Mr. Carnegie's gift.

IN the *Engineer* there is a long and interesting description of the instructive case of models showing the construction of the leading types of expansion and plain slide-valves lately placed on view in the Victoria and Albert Museum. The collection forms a complete record of the progress made in this important branch of steam engineering.

IT is reported in *Engineering* that the world's copper production in 1904 amounted to 613,125 tons, the United States furnishing more than half the total. Great things in the way of copper production are expected from Alaska, where development is being carried on rapidly, especially in Tanana County. In the same journal, attention is directed to an important discovery of tin ore in the Vlaglaagte district of the Transvaal. The world's sources of tin supply are so few that interest must always attach to reported new finds.

WE have received a copy of a paper reprinted from the *Transactions of the Institution of Mining Engineers*, read on January 10, by Mr. James Ashworth, on outbursts of gas and coal at the Morrissey collieries, in the Crow's Nest Pass Coalfield, British Columbia. A huge outburst on November 18, 1904, caused the death of fourteen miners, and it is estimated that some 3,000,000 cubic feet of gas, at atmospheric pressure, were set free by the outburst in thirty-five minutes. Mr. Ashworth suggests that these unusually large outbursts may have some connection with the petroleum occurring in the district.

AT the forty-second general meeting of the Institution of Mining Engineers, held in London on June 2 and 3, several interesting papers were read. Mr. T. Y. Greener dealt with the firing of boilers by waste heat from coke ovens. Mr. M. R. Kirby described the compound winding engine at Lumpsey iron mine. Its steam consumption is only 38 lb. to 40 lb. per indicated horse-power hour. Mr. F. Hird gave the results of tests of the electric winding engine at Friedrichshall, and Mr. E. Lozé described electric winding engines installed at French collieries. Mining

education in the United States was discussed by Prof. H. Eckfeldt, and in New Zealand by Prof. J. Park. Coal mining in India was dealt with by Mr. T. Adamson. Mr. J. Jeffries described the occurrence of underground fires at the Greta colliery, New South Wales. Mr. W. C Blackett and Mr. R. G. Ware described a striking innovation in mining practice, the use of electrically driven mechanical conveyors for filling at the coal-face. Two years' experience has shown a saving of 48 per cent. over the ordinary pick and shovel method. Lastly, Mr. A. R. Sawyer gave an account of the geology of Chunies Poort, Zoutpansberg, Transvaal. Incidentally, he mentioned some old copper workings where native copper occurs in some abundance in dolomite. The proceedings terminated with a vote of thanks, proposed by Mr. Bennett H. Brough, to the Geological Society and to the Royal Astronomical Society for the use of their rooms for the meeting.

IN the *Biologisches Centralblatt* of May 15 Dr. O. Zacharias brings to a conclusion his article on the relations of modern hydrobiology to fish culture and fisheries. Dr. G. Schneider also discusses the origin of species among cestode worms. He concludes that morphological variation in union with biological isolation through parasitism are insufficient to form species unless aided by physiological, that is, sexual, isolation.

IN the *Nouveaux Mémoires* of the Moscow Academy, vol. xvi., parts ii. and iv., the well known Russian ornithologist, Dr. P. Suschkin, commences an important work on the osteology of the avian skeleton, the second part, which is alone before us, dealing with the osteology and classification of the diurnal birds of prey (Accipitres). This part is illustrated with four plates of various parts of the skeleton.

DURING a recent visit to the Victoria Falls of the Zambezi, Mr. W. L. Sclater, director of the South African Museum, obtained three fishes from that river which were sent to the British Museum for examination. One of these proved to be new, and is described by Mr. G. A. Boulenger in vol. iii., part vii., of the *Annals of the South African Museum* under the name of *Paratilapia carlottae* The genus is widely spread.

WE have received from the author, Mr. C. C. Hurst, a copy of his paper on experimental studies on heredity in rabbits, published in vol. xxix. of the *Journal of the Linnean Society*. The experiments were commenced in 1902, with the object of ascertaining whether the Mendelian principles of heredity were applicable to animals as well as plants, the animals selected being the white Angora rabbit and the Belgian hare. The results confirm, and extend to rabbits, those already obtained by Prof. Cuénot in the case of mice, though it would appear that the heredity of Dutch markings in rabbits differs in some respects from that of the "panachure" in mice.

IN the *Zoologist* for May, Mr. J. H. Gurney records the early history of a young cuckoo. On May 22 last year a hedge-sparrow's nest was found containing three eggs laid by the owner, and one egg deposited by a cuckoo. The cuckoo's egg was of the ordinary brown type, presenting no resemblance to the hedge-sparrow's eggs. On June 2 the young cuckoo and two hedge-sparrows were hatched, the third young hedge-sparrow, which had been hatched earlier, having previously disappeared. The next day the two nestling hedge-sparrows were found lying dead outside the nest. When one was replaced, no attempt was made to eject it by the cuckoo. The same result happened when a young wagtail was put into the nest; but when this was replaced by a young wren, the latter was ejected under the eyes of the observer in the usual manner. On June 22 the young cuckoo left the nest.

IN discussing certain habits of British bats in the eighth article of vol. xlix. of the *Memoirs of the Manchester Literary and Philosophical Society*, Mr. C. Oldham refers in the first place to the winter sleep, and points out that, from observations made in the disused copper mines of Alderley Edge, in the case of the long-eared bat this sleep is interrupted, the bats probably feeding at intervals on the insects which abound in the tunnels in winter, even if they do not venture forth into the open. The same is probably true of Daubenton's bat, the whiskered bat, and the lesser horse-shoe bat. There appears to be nothing to show that the bats occasionally seen abroad on mild days in winter are pipistrelles. Two popular fallacies are contradicted, firstly, that bats cannot walk, or can only shuffle awkwardly, along a flat surface, and secondly, that they cannot take flight from such a surface. The different

FIG. 1.—Lesser Horseshoe Bat in Repose.

postures assumed by British bats in repose form the subject of the plate illustrating Mr. Oldham's paper. The lesser horse-shoe bat, of which one of the figures is reproduced, recalls the posture assumed by the fox-bats, or flying-foxes, when at rest. The posture of ordinary bats is quite different, and it is a curious fact that while the lesser horse-shoe alights from the air in an inverted position, other bats, on first coming to rest, do so with the head upwards, and then reverse their position.

THE foregoing paper is supplemented by the observations of Mr. C. B. Moffat on the duration of flight among bats, published in the May number of the *Irish Naturalist*. In this communication it is shown that while the long-eared bat and the pipistrelle are all-night fliers, the hairy-armed bat only ventures forth for a short flight in the evening, and again shortly before dawn. The hairy-armed bat thus enjoys a daily rest of 21½ hours, taking all its exercise and its food in two periods (which in summer may be very close together) of one and a quarter hours each. There is a suggestion that the great bat, or noctule, indulges only in an evening flight, but additional evidence is required before this can be definitely accepted, and it appears to be contradicted by certain observations which the author did not see soon enough to incorporate in his text.

No. 1402 (vol. xxviii.), pp. 425–460, of the *Proceedings of the U.S. National Museum* contains descriptions by Mr. E. A. Mearns of new mammals from the Philippine Islands. The most interesting of these is a new genus of insectivore represented by *Podogymnura truei*. It is allied to Gymnura and Hylomys, and has a long hind-foot and a stout tail rather more than a third the length of head and body. Two tupaias are likewise referred to a new genus, Urogale, one of these having been previously described by Mr. O. Thomas as *Tupaia everetti*. They are characterised by the round tail. Several new genera of rats are likewise described, for one of which the author proposes the name Bullimus, a term, in our opinion, too like the familiar Bulimus. In vol. i., No. 6, of the *Bulletin of the Brooklyn Institute*, Dr. J. A. Allen describes a collection of mammals from Beaver County, Utah. Copies of three other American papers have been received during the current week. In the first, *Bulletin of the Brooklyn Institute*, vol. i., No. 6, Mr. C. Schaeffer records additions to the beetle fauna of the United States, with notes on some previously known species. In the second, *Proceedings of the U.S. National Museum*, No. 1400, Miss Richardson describes two new isopod crustaceans from California. In the third, *op. cit.* No. 1401, Mr. T. W. Vaughan gives a critical review of the genera of the fungoid corals, with a tentative classification.

When the "Book of Antelopes" was concluded in 1900 the authors were unable to give any satisfactory account of Heuglin's "giant eland" of the Bahr-el-Ghazal from the want of accessible specimens. Heuglin had described it in 1863, but had based his description on a single pair of horns, and Schweinfurth, who had subsequently met with the same animal in Bongoland, had given very little further information about it except that it had stripes on its body. In these circumstances Messrs. Sclater and Thomas classed the giant eland of Central Africa as a subspecies of the common eland (*Taurotragus oryx*) under the name *Taurotragus oryx gigas* ("Book of Antelopes," iv., p. 208). This splendid animal, which may be fairly called "the grandest of all the African antelopes," has lately been re-discovered by Mr. A. L. Butler, the superintendent of game preservation in the Anglo-Egyptian Sudan, who communicated a full description of it to the Zoological Society at a recent meeting. It appears, from the evidence given by Mr. Butler, that its nearest ally is the Derbian eland (*Taurotragus derbianus*) of Senegal, and not the typical *T. oryx*, and he therefore proposes to call it *Taurotragus derbianus gigas* instead of *T. oryx gigas*. This is probably correct, as the description given by Mr. Butler agrees very fairly in most points with the Derbian eland. But the giant eland appears to be a still larger and finer animal, with much stronger horns; its height at the withers is stated to be 68 inches. On this question we may shortly have an opportunity of forming an opinion, as Bimbashi Collins, of the Egyptian Army, who has himself shot two specimens of the animal, has sent the heads and skins to Mr. Butler to be forwarded to England, where they will probably go to the Natural History Museum at South Kensington.

The question of the sleep of fishes was referred to (p. 104) last week in our notice of the last volume of the "Cambridge Natural History." Mr. F. Davis, writing from 49 and 51 Imperial Buildings, Ludgate Circus, E.C., says that observations of many varieties kept by him in aquaria extending over a period of twenty years show that fishes do sleep. He has also observed what appeared to be the play or sports of fishes, which probably serves the same biological ends as in the higher vertebrates. He remarks:—"Apparently when kept in aquaria fishes only sleep during the hours of darkness. If an artificial light be thrown upon them they quickly regain consciousness."

We have received the annual report for 1903 of the Government bacteriologist and director of the laboratory (Mr. H. Watkins-Pitchford), Pietermaritzburg, showing that much good work is being done in the colony. It contains a valuable bacteriological report on the plague in Natal in 1902–3.

The "Nervous Diseases Research Fund" has just issued its first annual report. The object of the fund is to promote and carry on research into the origin and cure of diseases of the nervous system. The work is carried on at the National Hospital, Queen's Square, W.C., and is under the direct supervision of the medical staff of the hospital. During 1904, forty-eight autopsies were performed and the pathological condition investigated. Special attention has been directed to the study of a disease known as myasthenia gravis, which is almost invariably fatal, and about which little is known at present.

The development of lenticels at points where the stress is small is discussed by Mr. J. A. Terras in an article in the *Transactions and Proceedings of the Botanical Society of Edinburgh* (vol. xxii., part iv.), and the origin of lenticels on roots is described in some detail. A first account of new species of flowering plants from the Republic of Colombia, mostly collected by the writer, who accompanied Captain Dowding's expedition in 1898–9, is contributed by Mr. T. A. Sprague to the same number.

A recent leaflet issued by the Board of Agriculture and Fisheries furnishes an account of the life-history of the pine sawfly, *Lophyrus pini*, which attacks more especially the Scots pine and the black Austrian pine. Two broods develop in the year, the first in May and the second in August. The larvæ are the source of damage, as they devour the pine needles. Amongst the animals which feed on the larvæ are mice, squirrels, goatsuckers, and starlings, also numerous ichneumon flies. In plantations the best remedy is to kill the larvæ by hand, but as a spray for ornamental trees in parks and gardens, hellebore essence or arsenate of lead is recommended.

Although the investigation of the gametophytes and embryo of the gymnospermous genus Torreya has not yielded the critical results which had been expected, several interesting taxonomic characters were observed by Dr. J. M. Coulter and Mr. W. J. G. Land, and are described in their account of *Torreya taxifolia* in the *Botanical Gazette* (March). The archegonium initial is differentiated very early, while most of the endosperm develops after fertilisation. A pro-embryo of twelve to eighteen cells completely fills the egg and persists through the winter, until in the spring the suspensor elongates, and later the ruminated appearance of the endosperm becomes apparent. Rumination is shown to be due to the unequal resistance offered by the perisperm in different parts of the seed to the encroaching endosperm.

The report of the Meteorological Commission of Cape Colony for the half-year ending June 30, 1904, has been received. The usual tables of rainfall, temperature, &c., at various stations will not be published until the issue of the next half-yearly report, so that the data may be comparable with the information contained in previous yearly reports. But in lieu of the usual tables above referred to,

the present issue contains a very valuable series of twenty-three tables prepared by the secretary (Mr. C. M. Stewart) showing the characteristic features of the winds at the Cape Observatory during the five years 1896–1900, arranged under sixteen points of the compass, and referred to various elements, *e.g.* temperature, humidity, &c., and giving the percentage of relative wind-frequency and wind-force at various hours.

WE have received a copy of the report of the director of the Philippine Weather Bureau for the year ending August 31, 1904 (reprinted from the report of the Philippine Commission, part ii.). We have frequently had occasion to refer to the useful work of this organisation, and the valuable researches and publications of the Rev. J. Algué, S.J., particularly in respect of the cyclones in the Far East. The central office performs a large amount of work gratuitously for observers on land and sea, by adjusting and comparing instruments; this is generally only known to those benefited. The director states that the weather bureau is never closed; the chief officials live at the observatory, and are ready to attend any call at all hours, especially inquiries by officers of ships, if they wish for information as to the conditions of weather. In addition to the regular work, telegrams are constantly exchanged between the provinces, China, Formosa, and Japan, and when bad weather is impending special warnings are dispatched to the points threatened.

THE annual summary of the Monthly Weather Review of the U.S. Weather Bureau for 1904, containing a useful subject, author, and title index of the papers published in the monthly parts, and an annual climatological summary of the observations made at the Weather Bureau stations, has just reached us. Weather forecasts for thirty-six and forty-eight hours in advance have been made daily throughout the year for each State, and special warnings of gales on the sea coasts have been issued when necessary. In a number of instances, the chief of the Weather Bureau states, European shipping interests were notified of the character and probable course of severe storms that were passing eastward from the American coast. The warnings and indications of the movements of West India hurricanes have evidently been the means of saving a large amount of property and a number of lives, and their value has been acknowledged by the Press, and also by the President of the Jacksonville Board of Trade, who states that the warnings to vessels not to leave port prevented serious disasters. Prof. W. L. Moore expresses the hope that the time will come when it will be possible to forecast the weather generally for coming seasons, but that time has not yet arrived. Valuable researches are being made at Mount Weather Observatory, Virginia, where it is proposed, *inter alia*, to discuss meteorological observations from the point of view of their relations to solar physics, and to select meteorological and magnetic elements and compare them with solar observations.

IN the current number of the *Comptes rendus* of the Paris Academy of Sciences M. Guyou gives an interesting account of the utilisation of the telephone system for the exact transmission of time. The experiments were undertaken by the Observatory of the Bureau des Longitudes at the request of the Chambre syndicale de l'Horlogerie, and after a preliminary trial in the Paris area were extended to the whole French system. The transmission of the time by a verbal signal not being sufficiently exact for the purpose, by means of a specially arranged microphone each beat of the pendulum of the standard clock in the observatory could be heard in the telephone receiver, the operator at the sending end merely counting one or two beats. On May 25 the destroyer *Escopette*, whilst at Brest, was able to regulate its chronometers directly against the standard clock of the Observatory of Montsouris with an accuracy of about 0·1 to 0·2 second. As M. Guyou points out, owing to the wide extent of the telephone system at the present time, this mode of transmitting the time ought to be of considerable service.

IN *Kungl. Svenska Vetensk. Akad. Handl.* (Band 38, No. 5) Dr. Hasselberg gives the results of an investigation of the arc spectrum of tungsten. The region he has studied extends from λ 3477 to λ 5892. This is a continuation of the very useful series of publications by the same spectroscopist relating to the arc spectra of metals. The elimination of lines due to impurities was done by comparing the tungsten spectrum with those of other metals taken under similar conditions. In cases of close agreement between tungsten lines and those of other metals a special study was made of the lines with the object of establishing their coincidence or non-coincidence, and in the former case the probable origin of the common line was determined from a consideration of the relative intensities in the two spectra. In a comparison column are given the lines recorded by Messrs. Exner and Haschek for the same element. The strongest lines of this metal have been carefully compared with the Fraunhoferic lines, and cases of coincidence and probable identity noted.

IN our issue of July 28, 1904, we noted that Dr. H. M. Reese, of Yerkes Observatory, had published the results of some observations of "enhanced" lines in the Fe, Ti, and Ni spectra, wherein he supposed that he had discovered some enhanced lines not included in Sir Norman Lockyer's lists. In the current number of the *Astrophysical Journal* Mr. F. E. Baxandall comments on Dr. Reese's results, and shows that in a great number of cases there is no evidence of enhancement in the Kensington photographs. For example, the comparative tables given show for each element that of the seventy enhanced lines discovered by Dr. Reese for iron, fifteen are actually stronger in the arc than in the spark spectrum, twenty-five are equally strong in both spectra, twenty do not occur in either spectra on the Kensington grating spectrograms, whilst six are so slightly "enhanced" as to leave it doubtful as to whether they should be included in this category. It seems probable that Dr. Reese was misled by comparing two spectra of which the spark was generally the stronger, for he especially remarked that only one line was stronger in his arc than in his spark spectrum.

WE have received from the Bureau of Mines of Ontario an interesting memoir on the limestones of the province by Mr. Willet G. Miller, the provincial geologist. It covers 143 pages, and contains a number of excellent photographs of the principal quarries. It shows clearly where limestones of various chemical compositions are to be found, and gives a concise account of the uses of limestone and lime at the present time. Hitherto it has hardly been realised that limestones form an important part of the mineral resources of Ontario, and this well arranged collection of analyses of limestone and of descriptions of quarries cannot fail to prove of value to all interested in the important industries that depend upon limestone as a base.

MESSRS. ILIFFE AND SONS, LTD., have published a little book on practical frame-making by Colonel W. L. Noverre; the price is 1s. net.

OUR ASTRONOMICAL COLUMN.

PHOTOGRAPHIC REALITY OF THE MARTIAN CANALS.—No. 4021 of the *Astronomische Nachrichten* contains a telegram dated May 28 from Mr. Lowell to Prof. Pickering in which the former states that several of the canals on Mars have been photographed by Mr. Lampland. Amongst others, Nilo Syrtis, Casius, Vexillum, Thoth, Cerberus, Helicon, Styx, Chaos, and Liedeus (? Libneus) are shown on the negatives, some appearing on more than twenty plates.

DISCOVERY OF SATURN'S TENTH SATELLITE.—A brief note in No. 4015 of the *Astronomische Nachrichten* states that Saturn's tenth satellite was discovered from an examination of several plates taken with the 24-inch Bruce telescope which were selected from those used in the determination of the orbit of Phœbe.

The new satellite appears on thirteen plates. The orbital motion is direct and the period is twenty-one days, therefore the satellite is apparently a little nearer to Saturn than is Hyperion.

JUPITER'S SIXTH AND SEVENTH SATELLITES.—An abstract from vol. xvii. of the *Publications of the Astronomical Society of the Pacific*, appearing in No. 4015 of the *Astronomische Nachrichten*, contains an account by Prof. Perrine of the observations so far made of Jupiter's sixth and seventh satellites.

The former can be photographed in ten minutes with the Crossley reflector, and thirty-six plates have been obtained. A preliminary investigation of the orbit shows that the inclination to the ecliptic and the planet's equator is about 30°, and that the satellite has a period of about 250 days, with a mean distance from the planet of 7,000,000 miles. The direction of the orbital motion still remains uncertain. The brightness of the satellite indicates a diameter of about 100 miles, or less.

On examining the plates taken for the sixth satellite on January 2, 3, and 4, a much fainter object, also apparently belonging to Jupiter, was discovered, which was then situated N. and W. of, and was moving towards, the planet. Subsequent observations, which, owing to the satellite's faintness, were much more difficult to make than in the case of the sixth satellite, confirmed its dependence upon Jupiter. This object was not shown on the negatives taken for the sixth satellite during December, being just outside their field, but altogether twenty observations have been made, the last on March 9.

Apparently the orbit of the seventh satellite is quite eccentric, with a mean distance from the planet of about 6,000,000 miles and a period of about 200 days. The inclination of the orbit to the plane of Jupiter's equator is about 30°, but the direction of the orbital motion is as yet undetermined. The photographic magnitude of the seventh satellite is not brighter than the sixteenth, and on comparing this with the magnitudes of other satellites and of asteroids a diameter of about 35 miles is deduced.

Prof. Perrine suggests that the large inclination of their orbits indicates that neither of these bodies were originally members of Jupiter's family, but have been "captured" by the planet.

STARS WITH SPECTRA OF THE ORION TYPE.—In No. 2, vol. lvi., of the *Annals of the Harvard College Observatory*, the distribution of stars having class B or Orion-type spectra is discussed, and all known stars of this type placed in a catalogue, in order of R.A., the position (1900·0), magnitude, exact type of spectrum, and the galactic longitude and latitude being given for each star. Considerably more than 30,000 spectra have been examined by Mrs. Fleming in connection with the Henry Draper memorial work, and of these 803 are included in the present catalogue.

As a distinctive feature of these stars is the helium indicated in their spectra, the allocation of them with regard to galactic longitude and latitude really indicates the distribution of helium in the universe. On thus classifying them, it is found that on dividing the sky into equal areas the galactic latitudes of which are included between +90° and +30°, +30° and 0°, 0° and −30°, and −30° and −90°, the numbers of well marked helium stars in these divisions are 22, 219, 509, and 53, or 3, 27, 63, and 7 per cent. of the total respectively, nine-tenths of them being within 30° of the galactic equator. A congregation in certain galactic longitudes is also indicated. Thus between 160° and 340° there are 613, or 78 per cent. of the total, of these stars. About one-quarter of the whole number are contained in four regions having a total area of 790 square degrees, or less than one-fiftieth of the sky. One of these four regions is near to the variable star η Carinæ, and lies almost wholly within the constellation Argus. As this Argus region contains nearly three times as many "Orion" stars as does the Orion region, Prof. Pickering suggests that "Argus" stars would have been a more suitable generic name for the class of stars having spectra of this (B) type. He states, however, that the nebula of Orion appears to be the starting point, or origin, of class B stars, twenty of which are situated within 1° of θ Orionis, that is to say, nearly as many as are contained in the region between galactic latitudes +30° and +90°, although the area of the latter region is three thousand times as great.

Arranging them according to magnitude, it is found that most of this class are bright stars, only 1 in 20 being of the sixth or fainter magnitudes.

THE MOTION OF THE TAIL OF BORRELLY'S COMET (1903 iv).—From the examination of a number of photographs obtained by different observers during July, 1903, Prof. Jaegermann, Moscow, has compared the relative motions of the different sections of the tail of comet 1903 iv in regard to the movements of the comet's nucleus and to the sun. After analysing the velocities and movements determined, he has arrived at the conclusion that in this case light-pressure, acting in the sense of Arrhenius's hypothesis, was not the determining factor in the formation of the several tails, for a pressure sixty times greater than gravity would have to be assumed. If the light-pressure hypothesis be retained, the assumption must be made, according to Bredichin's idea, that the tail-matter consisted of gaseous molecules, and that its illumination was due to the fluorescence of highly illuminated gases, such as has been experimentally demonstrated by Lommel, Wiedemann, and Schmidt.

The existence of a repulsive force, other than light-pressure, was demonstrated by Bredichin in comet Rordame (1893 ii), by Prof. W. H. Pickering in comet Swift, and was confirmed by Prof. Jaegermann in a preliminary investigation concerning the denser parts of the tail of comet Swift, 1892 i.

DOUBLE STAR OBSERVATIONS.—The results of a series of observations of double stars made at Kirkwood (Indiana) Observatory are given in No. 4022 of the *Astronomische Nachrichten*. The observations were made by Mr. J. A. Miller and Prof. W. A. Cogshall with a 12-inch refractor, and the B.D. and A.G. numbers, the 1875 position, the magnitudes, and the measured position-angle and distance are given for each of 114 double stars.

The objects observed were selected from those noted as double by the Leipzig observers when preparing the A.G. catalogue for the zone +10° to +15°, and, with few exceptions, they have not been measured elsewhere. Some few stars suspected by the Leipzig observers as duplicate could not be seen as such by the Kirkwood observers, and one or two of the sets of measures refer to newly discovered double stars.

THE ROYAL OBSERVATORY, GREENWICH.

ON Saturday last, June 3, the Board of Visitors made their annual inspection of the Royal Observatory, Greenwich, but unfortunately, through ill-health, the Astronomer Royal was not able to be present. The following is a brief abstract of the report which was submitted to the visitors.

Very great progress has been made in the observation of the reference stars for the Greenwich section of the Astrographic Catalogue, about 9500 observations of R.A. and N.P.D. having been added during the year. The comparatively few observations required to secure five observations of each of the reference stars (more than 10,000 in number) will easily be obtained by the end of the year, as there are only 5 stars requiring three observ-

ations, 100 requiring two, and 1500 requiring one observation only in order to carry out the programme. In fact, it may be taken that the observations for this catalogue are practically completed. The catalogue, which will be terminated this year, will contain, besides the reference stars for the Astrographic Catalogue, the 834 zodiacal stars given in the Nautical Almanac for 1897.

It is proposed to begin next year a new nine-year catalogue of the stars of magnitude 9·0 and brighter between the limits +24° to +32° of N. declination, this being the Oxford astrographic zone, for which they serve as reference stars. The re-observation of these stars, which for the most part fall within the Cambridge zone of the Astronomische Gesellschaft Catalogue, will afford valuable data for their proper motions, besides giving fundamental positions for the Oxford astrographic plates.

The comparison between theory and the Greenwich meridian observations of the moon from 1750 to the present time, undertaken by Mr. Cowell, has been completed for the longitudes, and the discussion from 1847 to 1901 is completed for the latitudes. The only point left outstanding is the motion of the node, for which it is necessary to discuss as long a series of observations as possible. The results obtained for the longitudes are summarised in a series of papers in the *Monthly Notices of the Royal Astronomical Society*. In particular, the paper in vol. lxv., No. 2 (1904 December), gives the coefficients of 145 terms as obtained directly from observation, with a comparison with the theoretical coefficients given by Hansen, Delaunay, M. Radau, and Dr. Hill. The publication of the details of the whole investigation will be shortly proceeded with.

The re-reduction of Groombridge's observations was completed at the date of the last report, and during this year the printing of the results has been pushed on. The introduction has also been prepared for press. A discussion of the proper motions determined by comparison with modern Greenwich observations, and a determination of the constant of precession and of the direction of the solar motion by Mr. Dyson and Mr. Thackeray, are given in the *Monthly Notices of the Royal Astronomical Society*, March.

The altazimuth has been in regular use throughout the year, and a second determination of the pivot errors has been made, and also observations for obtaining the value of one revolution and errors of the screw of the telescope-micrometer have been completed.

The observations of the moon, both in and out of the meridian, seem very satisfactory as shown by the agreement between the two instruments, the transit circle and the altazimuth.

The 28-inch refractor has been employed, as was the case last year, for micrometric measurements of double stars, the total number measured being 603. Of these, 143 have their components less than $1''\cdot0$ apart, and 60 less than $0''\cdot5$. A marked deterioration of the images of the stars led to an examination of the lenses, and the suspected tilt between the components was corroborated and remedied.

Sixty-five photographs of Neptune and its satellite have been secured with the 26-inch refractor, while, with the 30-inch reflector, numerous photographs of minor planets and comets *a*, *b*, *c* 1904, and *a* 1905, have been obtained.

At the date of the last report, 119 plates taken of Eros with the astrographic equatorial, and 55 taken with the Thompson equatorial, had been measured. During this year the remainder of the photographs have been measured, making in all 198 with the astrographic equatorial and 152 with the Thompson instrument. The reduction of the measures is in a satisfactory state, and it is expected that it will be completed in two months for both sets of photographs.

The astrographic equatorial has been employed mainly to obtain photographs to replace chart plates which show slight photographic defects unsuitable for production of enlarged prints.

The measurement of the catalogue plates for the Greenwich section is now completed. Since the last report 47,200 measures of pairs of images (6m. and 3m.) have been made. The number of plates measured in the year is 102, covering 128 square degrees between declination 83° and the pole. The number of plates measured up to the date of last year's report was 1051. Adding the 102 plates measured this year, the total number of plates measured is 1153, being the 1149 of the Greenwich section + 4 additional photographs of the polar field.

For the year ending 1904 December 31, Greenwich photographs of the sun have been selected for measurement on 209 days, and photographs from India and Mauritius (to fill up the gaps in the series) on 151 days, making a total of 360 days out of 366 on which photographs are at present available. Photographs were taken in Mauritius for three of the six days yet unrepresented, and may be received in due course.

The solar activity has shown a great increase during the year ending 1905 May 10, and the sun has not been free from spots on a single day during that period. The mean daily spotted area for 1904 was more than half as great again as that for 1903, and early in the present year a number of exceptionally large groups was observed. The group which was seen first on the east limb on 1905 January 28 had a greater total area than any other group which has been photographed at the Royal Observatory.

The principal results of the magnetic elements for 1904 are as follows:—

Mean declination	16° 15'·0 West.
Mean horizontal force	4·0166 (in British Units). 1·8520 (in Metric Units).
Mean dip (with 3 needles) ...	66° 57' 11".

In 1904 there were no days of great magnetic disturbance and eight of lesser disturbance.

The mean temperature for the year 1904 was 49°·8, or 0°·3 above the average for the fifty years 1841–90. During the twelve months ending 1905 April 30 the highest temperature in the shade (recorded on the open stand in the magnetic pavilion enclosure) was 91°·0, on August 4. On the same day the highest temperature in the Stevenson screen in the magnetic pavilion enclosure was 89°·5, and in the observatory grounds 89°·7. The lowest temperature of the air recorded in the year was 19°·5, on January 1. During the winter there were thirty-nine days on which the temperature fell below 32°·0, being seventeen less than the average number.

The mean daily horizontal movement of the air in the year ending 1905 April 30 was 280 miles, which is 2 miles below the average of the preceding thirty-seven years. The greatest recorded daily movement was 867 miles, on November 9, and the least 49 miles, on December 22. The greatest recorded pressure of the wind was 23·5 lb. on the square foot, on March 12, and the greatest hourly velocity 45 miles, on December 30.

The number of hours of bright sunshine recorded during the twelve months ending 1905 April 30, by the Campbell-Stokes instrument, was 1486 out of 4457 hours during which the sun was above the horizon, so that the mean proportion of sunshine for the year was 0·333, constant sunshine being represented by 1.

The rainfall for the year ending 1905 April 30 was 20·21 inches, being 4·33 inches less than the average of the fifty years 1841–90. The number of rainy days was 153. This small rainfall may be contrasted with the heavy rainfall of 35·42 inches in the corresponding period last year. The most striking contrast is obtained by comparing the rainfall for the year commencing 1903 March 1, which was more than 37 inches, with that for the year commencing 1904 March 1, which was less than 17½ inches. This dry period of twelve months was followed by a heavy rainfall in 1905 March, which exceeded 3½ inches, and is the greatest amount recorded in March since 1851.

The printing of the Paris-Greenwich longitude determination, 1902, is practically complete. The Killorglin longitude is the only determination which still requires to be printed to complete the volume of longitude determinations, which will contain the determinations Paris-Greenwich made in 1888, 1892, and 1902, of Greenwich-Waterville-Canso-Montreal made in 1892, and of Greenwich-Killorglin made in 1898.

The re-reduced Groombridge Catalogue is nearly completely printed, with the exception of the introduction, which is ready for the press.

Provision has been made in the Navy Estimates for the observation of the total solar eclipse of 1905 August 30 by a party of three observers on the coast of Tunis, where the weather conditions are promising. It is proposed to take photographs of the corona for detail and extension with the Thompson 9-inch coronagraph, the 13-inch astrographic refractor, and the 4-inch Dallmeyer rapid rectilinear lens, and also photographs of the spectrum with the two spectroscopes lent by Major Hills, R.E., as in 1900 and 1901.

THE OPTICAL CONVENTION.

THE optical convention has just concluded a very successful meeting extending over four days; the exhibition and the papers attracted numerous visitors from all parts of the country. The papers led to much valuable discussion. An account of the exhibition and the president's address appeared in last week's NATURE.

The first group of papers dealt with the design of optical and scientific instruments. The Gauss theory was entrusted to Mr. Conrad Beck, who considered the theory of the equivalent planes of complete optical instruments; he dealt more particularly with the complete microscope in relation to its "working distance."

Dr. Drysdale gave a general account of the aberrations of lens systems, submitting a classification and specification of the various aberrations to obtain an expression of opinion from those working at the subject. Mr. Chalmers gave a graphical method of representing the results of calculations of lens systems, and a modification of the Hartmann system of testing to permit of measuring and expressing aberrations in exactly the same form. This should make it possible to obtain the relation between the definition and the measured or calculated aberrations. In the discussion Mr. Carson pointed out the importance of the relative intensity of the image disc and the aberration patch in estimating the performance of lenses.

Mr. Walter Rosenhain criticised the mechanical design of certain types of instruments; he showed that, in many cases, the ideals of the instrument maker were in conflict with sound engineering principles, and suggested directions in which improvements might be looked for.

Diffraction in optical instruments was discussed by Mr. J. W. Gordon in an important theoretical paper; his conclusions, which would modify many of our ideas on optical systems, are now being submitted to a definite experimental test.

A group of papers related to interference phenomena. Mr. J. Rheinberg exhibited a method of producing achromatic interference bands which is likely to have numerous applications. Mr. Stansfield described a simple form of Michelson interferometer specially suitable for demonstration. Prof. Watkin and Mr. Morrow exhibited their apparatus for calibrating extensometers by observing the displacement of interference bands.

Mr. Twyman described the manufacture of the Echelon spectroscope, stating the accuracy required in the plates and the precautions used to obtain it. This apparatus was exhibited and compared with the Lummer "parallel plate" arrangement for obtaining resolution of spectrum lines. Mr. Blakesley discussed the various forms of prism which could be used in constant deviation spectroscopes and some of their applications. Mr. Newall dealt with astronomical spectroscopes, demonstrating that the limits of usefulness of the present type of spectroscope were almost reached in the case of faint stars, as the intensity of light necessary for photographing their spectra can only be obtained at the sacrifice of the purity of the spectrum or the certainty of identification of the lines, and that no very marked improvement is likely to be obtained from the use of larger objectives, on account of the increased absorption in the prisms required. He suggested the use of gratings.

Lord Rayleigh dealt with the subject of polish, pointing out the distinction between the process of grinding, which consists of the removal of comparatively large flakes, and that of polishing, which he regards as molecular, the roughnesses of the surface being reduced to dimensions smaller than the wave-length of light. Experiments on the thickness of glass removed by polishing and by etching with hydrofluoric acid under various conditions were illustrated. In the discussion Mr. Walter Rosenhain cited evidence to show that the surface flow which has been recognised in the polishing of metals also occurs in glass.

Mr. Walter Rosenhain dealt with the possibilities of progress in optical glass; he described the limitations to the production of vitreous fluxes of extreme properties, and advanced the view that media of widely different optical properties could only be obtained by the production of large homogeneous crystals. Physicochemical considerations were cited to indicate lines upon which this difficult problem might be solved.

A number of instruments for optical measurements were described, Prof. Poynting exhibiting his form of parallel plate micrometer. Mr. Blakesley described his apparatus for the measurement of focal length of lenses, with applications to other optical measurements. Mr. Chalmers described a new form of refractometer for obtaining the refractive index of glass in lens form. The lens is inserted in a trough containing a suitable transparent liquid, and the difference of the refractive indices is deduced from the approximate curvatures of the lens and its power in the liquid, with an accuracy comparable with that of the best refractometers.

Mr. Baugh described the use of invar tapes for base-line measurements.

Dr. Drysdale discussed the requirements of small telescopes and binoculars, with special reference to the field of view and illumination of the image. He indicated the method he had employed in calculations for prism binoculars, showing how he had been led to use glass of high refractive index for the prisms. He described a special form of photometer for determining the absorption in binoculars.

Mr. A. C. Jolley gave a critical review of photometric standards and apparatus; he described a modification of the Violle platinum standard, and discussed the difficult problems connected with heterochromatic photometry; his results indicate that the accuracy claimed by Sir W. Abney is far too high, especially when readings by different observers are compared. He concludes that a discrimination photometer is the most trustworthy instrument for comparing different colours.

Mr. Milne exhibited his new form of spectrophotometer. The apparatus is especially suitable for determinations of the absorption of light of specified wave-length by liquids.

Mr. Bull discussed the theory of tricolour filters, plates, and inks. He concluded that it was most satisfactory to adjust each independently of errors in the adjustment of the others. The filters should have a certain amount of overlap, the colour of the overlap of two filters being the colour of the printing ink corresponding to the other filter.

Mr. Crawley discussed the limits of stereoscopic vision; the results of his measurements point to a much greater accuracy in judging distances by stereoscopic effect than is generally admitted.

Mr. H. L. Taylor discussed the effects of astigmatism on the accommodation of the eye. Two new forms of ophthalmometer were demonstrated, one being the Ettles-Curties, which is valuable for the perfection of its mechanical adjustments, and the use of complementary colours for the mires; it is so arranged that the corneal microscope can be readily attached. The ophthalmometer shown by Mr. Sutcliffe contains a number of variations from ordinary forms; the mire is an almost complete ring illuminated by a special lamp, and the method of doubling the image is novel.

Dr. Walmsley gave an account of the attempts which have been made to provide technical education for those engaged in the optical industry, and the existing facilities; he outlined the scheme for the establishment of a British Institute of Technical Optics. The convention decided to memorialise the London County Council to support the scheme.

Major-General Waterhouse gave an account of the history of telephotography.

In the evening lecture, Prof. Silvanus P. Thompson gave a most interesting account of the various forms of Nicol's prism and its modern equivalents.

AGRICULTURAL NOTES.

THE annual report of the Transvaal Department of Agriculture for 1903–4 is a volume of more than 400 pages, which contains, in addition to an introduction by the director, reports on the fourteen sections into which the work of the department falls. In discussing the *personnel* of the department, the director refers to the difficulty of obtaining expert assistants, a difficulty which, so far as agriculture is concerned, exists in all countries supplied from Britain, and even in such countries as the United States, where the training of the expert receives more attention than it does here. Many of the chief positions in the Transvaal department have now been filled up, but assistants are still required, and as the work expands it is probable that a considerable number will be engaged. The report states that men for scientific work "will doubtless best be obtained from amongst students who have had good careers at one or other of the universities, and who have done a certain amount of research after taking their degree. A thorough grounding in pure science is a *sine qua non,* and if they are not acquainted with the applied side of Science, this knowledge will have to be acquired in our laboratories whilst acting as assistants to the Chief of their particular Division."

The above named report contains many interesting paragraphs. Here is one that appears under the heading "Farmers' Cooperative Experiment Reports":—From General Louis Botha, Pretoria, "They (mangels from England sent for trial by the Department) do not grow so quickly as other sorts of root-crops, but if sown early they will grow splendidly and give a good winter crop in May; therefore I ordered a big quantity which I intend to use this year."

In papers contributed to the first four parts of the *Agricultural Journal of the Cape of Good Hope* for the current year, Mr. D. E. Hutchins, conservator of forests at Cape Town, makes out a strong case for the extension of tree planting in South Africa. The coast districts have a very favourable climate, growth is rapid, and the quality of the timber produced is good; but while native resources have not been developed, timber to the value of 1½ millions is imported annually. There is no reason why most of the wood required for building and mining purposes should not be grown in the country, and it is estimated that every 1*l.* spent in afforesting suitable land would bring in an annual revenue of 1*l.* in thirty-five years' time! If Mr. Hutchins can convince the financier that this estimate is correct, South Africa should soon grow its own timber; but in this branch of agriculture the sower seldom reaps, and the investor is not easily convinced. It is likely, therefore, that in South Africa, as elsewhere, the lack of capital will prove a more serious difficulty to the enthusiastic forester than either soil or climate.

In a recent number of the *Bulletin of the College of Agriculture, Tokyo Imperial University,* there is an article of considerable interest to British agriculturists. The Japanese farmer, like the English farmer of half a century ago, is given to employing lime more freely than is good for his land, and in some districts the injury done by liming has caused the authorities to interfere with the practice. Following up some work by Kellner and Böttcher on the effects of lime on the action of certain phosphates, Nagaoka investigated the results of employing a number of phosphatic fertilisers on limed and on unlimed land. Rice was grown, and it was shown that lime greatly interfered with the action of those phosphatic manures which were of animal origin, such as bone meal or fish bones; on the other hand, when the phosphates were derived from a vegetable source, the effects of lime were not very pronounced. The injury was about twice as great in manures of animal as in those of vegetable origin. The injurious action of lime extended into a second year. Nagaoka's results confirm those obtained by Kellner and Böttcher in Germany, and indicate that such manures as bone meal and fish meal should not be used on recently limed soils.

We have received from the committee of the Lawes Agricultural Trust a copy of the report of the director, Mr. A. D. Hall, on the work done at the Rothamsted Experimental Station for the year ending March 31. The well known experimental fields are still continued without any essential change; in addition, a new field has been laid out to test the residual value of various manures in the second and succeeding years after their application. Other experiments deal with calcium cyanamide, the new manure containing nitrogen derived from the atmosphere, and with the various cultivations of bacteria which have been recently introduced for the inoculation of leguminous crops, with the view of making them more efficient collectors of atmospheric nitrogen. During the year in question seven papers have been issued from the station, all of which deal with investigations on the soil, methods of soil analysis, &c. The annual losses of carbonate of lime in the Rothamsted soil have been determined, both that due to natural agencies and that caused by the use of manures. Certain restorative actions have been investigated which account for the maintenance of the fertility of many soils which are almost devoid of lime. Another of the papers deals with the remarkable accumulations of fertility in certain plots of land which have been allowed to run wild for the last twenty years, and have in that time gained nitrogen to an extent not readily explicable by the accepted theories. The Lawes Trust committee continues to find its income very inadequate to the proper development of the station; only donations and subscriptions from various sources, including 300*l.* from the Goldsmiths' Company, 50*l.* from the Clothworkers' Company, 50*l.* from Lord Rothschild, &c., have prevented a serious deficit on the year's working. Mr. J. F. Mason has also promised to erect and equip a new laboratory for agricultural bacteriology, which will be the first of its kind in this country, as a continuance of the experiments carried on for many years by his father, the late Mr. James Mason, at Eynsham Hall, Oxon.

REPORTS ON SEA FISHERIES.

THE report for 1904 on the Lancashire Sea Fisheries Laboratory at the University of Liverpool and the sea fish hatchery at Piel[1] contains an introduction and general account of the year's work, written, as usual, by Prof. Herdman, the honorary director of the scientific work.

A report upon the sea fish hatchery at Piel, by Mr. Andrew Scott, shows that more than a million plaice fry and more than twelve million flounder fry were liberated, the result of hatching eggs laid by fish caught in the autumn and confined in tanks at the hatchery. The useful results to the fisheries of thus confining spawners and turning out the newly hatched fry have yet to be demonstrated.

A paper upon the tow-nettings collected in the Irish Sea, contributed by Mr. Scott, is of little value, because it is far too general, the contents of the tow-nets not having been identified. Such records as "Copepoda, medusoids, gelatinous algæ, a fish egg," are perhaps of some value, but of very little. It appears to us that had less been attempted, and some one group properly worked, the value of the paper would have been much greater. In referring to the occurrence of pelagic fish eggs, the scientific names of the various species might have been mentioned with advantage.

Bacteriological investigations in relation to shell-fish pollution by sewage matter, by Mr. James Johnstone, is an interesting paper continuing an investigation carried on during the previous year. Mr. Johnstone is also responsible for a paper upon plaice-marking experiments, and for another upon the internal parasites and diseased conditions of fishes. The plaice-marking experiments are upon a small scale, but no doubt will give results of interest in time. Dr. J. Travis Jenkins, recently appointed to the post of superintendent of fisheries of the district, contributes an interesting discussion of official fishery statistics, from which it appears that the Board of Trade returns are not always accurate. Dr. Jenkins's remarks

[1] Report or 1904 on the Lancashire Sea Fisheries Laboratory at University of Liverpool and the Sea-fish Hatchery at Piel; and Syllabu Lessons on Marine Biology. (Liverpool, 1905.

upon the cockle industry are both interesting and important.

The volume contains several plates and woodcuts, and is in paper covers. The education committee of the Lancashire County Council provided funds for the instruction of fishermen at the Piel hatchery, and forty-five fishermen attended the class which was held in the spring by Mr. James Johnstone. A "Syllabus of the Lessons in Marine Biology given in the Practical Classes for Fishermen" has been revised, and is now published as a separate volume. It is difficult to estimate the value to the fishermen of the benefit to be derived from a superficial knowledge of marine biology, but the value to the laboratory no doubt lies in the fact that the men send in specimens of animals and plants taken in the course of their fishing operations.

The Danish fishery and hydrographical contributions to the international North Sea fisheries investigations,[1] lately issued, include two papers dealing with fishery matters, one by Mr. Johs. Schmidt being concerned with the pelagic post-larval stages of the two species of halibut *Hippoglossus vulgaris*, Flem., and *H. hippoglossöides* (Walb.). Mr. Schmidt points out that the best distinction between these two species is not in the number of fin-rays, but in the number of vertebræ, and he found certain post-larval fishes off Iceland and the Færöe Islands which agreed in the number of vertebræ with the adults of *H. vulgaris*. The material from which he determined the young stages of *H. hippoglossöides* was taken by the Danish Ingolf Expedition.

The other fishery paper is by Dr. A. C. Johansen, and is entitled "Contributions to the Biology of the Plaice with Special Regard to the Danish Plaice Fishery," and is the first report published upon the subject. The paper is exceedingly interesting, the results, chiefly in regard to the growth and migrations of the plaice, having been obtained by recording the length of a number of fish, marking them with a label, and returning them to the sea to be caught later on by one of the numerous fishing boats. A fair percentage of the fish have been recovered, and by re-measuring these fish their rate of growth during the time between their marking and re-capture has been determined. An interesting part of this experiment was the transplanting of fish from one ground to another, by which it was found that on some grounds they would grow three or four times as rapidly as upon other grounds. Experiments upon the same lines have been carried out by the English staff with similar results, but the official English report is not yet published. The marking experiments have also shown that in Danish waters there are decided migrations of plaice at different times of the year, the tendency being for the fish to work into shallower water during the spring and into deeper water during the autumn.

Dr. Martin Knudsen contributes a paper upon the hydrography of the North Atlantic Ocean, while Mr. J. N. Nielsen writes upon the hydrography of the waters of the Færöe Islands and Iceland during 1903. In both these papers we should have liked to see either an introduction stating the objects of the investigation or a summary of results, as, to those who are not hydrographers, the results obtained are not very clearly set forth. It is perhaps too early to attempt to connect the observed physical phenomena with the movements of the fish, but no doubt, as more material comes to hand, the biological results of the international investigations will be shown to be closely dependent upon the physical conditions observed by the hydrographical staff.

A paper by Mr. Neils Bjerrum, on the determination of oxygen in sea-water, is bound in with Mr. Nielsen's paper already referred to. Mr. Bjerrum has adopted a method of "preserving" the water samples taken in mid-ocean until they can be accurately analysed on land, and it appears that his method of adding to the water samples a solution of manganous chloride and caustic soda containing iodide of potassium has been very satisfactory.

FRANK BALFOUR BROWNE.

[1] Meddelelser fra Kommissionen for Havundersøgelser. (Copenhagen, 1904-5.)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—A statute was brought before Congregation on June 6 to provide a delegacy to superintend the instruction of candidates for the Indian Forest Service, and to grant diplomas in forestry. The proposal to establish a diploma in forestry in the university has arisen from the recent decision of the Secretary of State for India to send the Indian forestry students, hitherto trained at the Coopers Hill Engineering College, to receive their special training in forestry at Oxford. Those students under the regulations just issued by the India Office will be selected by a competitive examination held by the Civil Service examiners every summer. They must be natural born British subjects of not less than eighteen or more than twenty years of age on the January 1 before their selection. They will be required, before becoming candidates, to have passed Responsions or an equivalent examination. The subjects of the competitive examination will be:—(1) mechanics and physics; (2) chemistry; (3) zoology; (4) botany.

After selection the students will be probationers for about three years. For the first two years they will be required to study at Oxford, and their course will include theoretical and practical forestry, and subjects auxiliary to forestry, viz. organic chemistry and the chemistry of soils, geology, forest botany, forest entomology, mathematics, German, and book-keeping. During the third year of probation they will receive practical instruction, visiting Continental forests under suitable supervision. The first competitive examination will be held on August 29 for the selection of not less than nine candidates. Applications for admission must be made to the India Office by July 1.

The Junior Scientific Club gave a conversazione in the museum on Tuesday, May 30, at which more than a thousand visitors were present. Lectures and demonstrations were given by Prof. Poulton, Dr. Tutton, Dr. Brereton Baker, and Mr. E. P. Poulton, and there were a large number of scientific exhibits.

The Robert Boyle lecture for 1905 was given by Sir Victor Horsley on Monday, June 5, in New College Hall. The subject of the lecture was "The Cerebellum."

CAMBRIDGE.—A little pamphlet has just been published on the authority of the Vice-Chancellor containing the names of all those who voted on the report of the examinations and the way they voted. An analysis of the poll shows that amongst the resident members of the university 288 voted in favour of allowing a substitute for Greek in the previous examination and 240 against. Thus the residents had, out of a total of 528 votes, the substantial majority of 48; they were, however, swamped by the non-resident vote. Only four colleges, King's, Christ's, Trinity, and Downing, showed a majority amongst both residents and non-residents in favour of the proposed change.

Prof. Lewis gives notice that a course of lectures and demonstrations in crystallography will be given in the mineralogical lecture-room during the long vacation, beginning at 9 a.m. on Friday, July 7.

The observatory syndicate has reported upon the management of the sum of 5000*l*. bequeathed by the late Mr. Frank McClean for "improving the instrumental equipment of the Newall Observatory." It recommends that the sum be invested, and that the disposal of both the interest and, if advisable, the capital, be in the hands of the syndicate, and that the accounts be annually audited and published with the university accounts.

The special board of medicine has drafted ordinances which, if they pass the Senate, will allow a candidate for the M.B. or M.D., if resident abroad, to take his degree *in absentia*.

THE annual conversazione of University College, London, will be held on the evening of Wednesday, June 28. There will be scientific and other exhibits illustrating the work of the various departments of the college.

MR. E. BROWN, lecturer on applied mechanics at the University of Liverpool, has been appointed assistant professor in civil engineering and applied mechanics in the McGill University at Montreal.

DR. J. E. DUERDEN, of the University of Michigan, formerly curator of the museum, Jamaica, has been appointed professor of zoology at the Rhodes University College, Grahamstown, Cape Colony.

A COURSE of eight lectures in advanced zoology on "The Prosobranchiate Mollusca" is being given in connection with the University of London in the lecture room of the Chelsea Physic Garden by Mr. J. E. S. Moore on Mondays and Thursdays during June. There is no fee for the course; cards of admission and a detailed syllabus may be had on application to the academic registrar, University of London, South Kensington, S.W.

THE King has approved the charter for the constitution of the University of Sheffield. On June 3 the Pro-Chancellor formally handed over the charter to the Vice-Chancellor, Dr. Hicks, F.R.S., and congratulatory speeches were made. The King and Queen have consented to open the new university buildings in July. An endowment fund of about 140,000*l.* has been raised in Sheffield, and the City Council and the councils of neighbouring boroughs and counties have guaranteed annual rate aid equivalent to an even larger capital sum. The first Chancellor of the university is the Duke of Norfolk.

WE learn from *Science* that Prof. Asaph Hall, jun., has resigned the professorship of astronomy and directorship of the observatory at the University of Michigan. Prof. W. T. Hussey, of the Lick Observatory, has been elected his successor. Prof. S. J. Barnett, of Stanford University, has accepted the chair of physics at Tulane University, vacant by the resignation of Dr. Brown Ayres to accept the presidency of the University of Tennessee. At Williams College, Mr. W. E. McElfresh has been promoted to the Thomas T. Reed professorship of physics, and Mr. H. L. Clelland to a professorship in geology. M. Gabriel Bertrand has been appointed to succeed the late M. Duclaux as lecturer on biological chemistry at the Paris Faculty of Science.

IT is announced, *Science* states, that 360,000*l.* has been contributed toward the endowment of 500,000*l.* which is being collected to increase the present amount available for the salaries of the teaching staff of the college of Harvard University. The circular which appeals for additional subscriptions says:—"The position of Harvard to-day among American universities is due not so much to its age, traditions, or able administration as to its noble line of teachers. That the teachers in the college should be the best in the land; that the older professors should be free from the cares of a straitened income; that the younger teachers should be able to give themselves without distraction to their work, and that the best men should not be drawn away to other colleges, but should see before them reasonable promotion in work and salary, is essential to the leadership of Harvard and the culture of her sons." It is pointed out that the total of salaries in Harvard College is about 87,600*l.*, and the average per capita allowance for the staff of 279 teachers is only 314*l.*

AN article entitled "Some Candid Impressions of England" is contributed to the current number of the *National Review* by a "German Resident." The first fact which strikes the contributor is the indifference of Englishmen to their individual duties as citizens of a great Empire, and it seems to him, looking at English schools, that the mainspring of German success is here. He says:—"Our youths, like your youths, are human, and would be lazy if there were no penalty for idleness. But the fact that those who are negligent and lazy at school have to put in an extra year of service, acts as a stimulus and compels the German boy to work, where the English boy spends his time in play." In another place:—"I look at England and see the want of such an influence even in your public schools, which are good in a way, so far as they form character, but bad in that they neglect intellect." As for our primary education, its product seems to the critic surprisingly bad. He says the knowledge imparted in our elementary schools does not seem to be such as is required for the making of good citizens. The majority of our workers, he remarks, read little but the sporting Press, and care for little but betting and sport. It is pointed out that the Germans have destroyed in this generation the superstition that Germany makes only poor and cheap articles. "Our Mercedes motors and scientific and optical instruments are the best and most expensive in the world, and no English article of their class can for a moment compete with them."

THE annual report of the council of the City and Guilds of London Institute was adopted at the yearly meeting of the institute held on June 1. The council directs attention to the diminished income of the institute, owing to the fact that the Mercers' Company, the Fishmongers' Company, and the Corporation have made reductions in their contributions. No reason, it is said, has been assigned for these reductions. At the invitation of the Lord Chancellor, a meeting of the representatives of the principal companies has been held to discuss the situation, and a resolution has been passed expressing a hope that the livery companies will increase, rather than diminish, their subscriptions. The total income for the past year, including donations for special purposes, amounted to 43,432*l.*, of which the Corporation and the livery companies contributed 23,308*l.*, the remainder coming from fees and other receipts. In the previous year the income was 46,829*l.*, of which the Corporation and livery companies contributed 29,385*l.* Sir John Wolfe Barry, in his speech moving the adoption of the report, alluded to an interview with the chairman of the Departmental Committee on the Royal College of Science, South Kensington. He gathered that the general idea of the scheme which will be submitted to the council of the institute is a federation or coordination of all the teaching institutions which are gathered round about South Kensington, and when this takes place the institutions will be in intimate connection with the university. It is held that a system of this kind will be a very great benefit, not only to the general teaching given, but also to post-graduate teaching, which will be largely developed, it is hoped, in the future.

THE report of the Commissioner of Education for the year 1903 has now been published by the United States Bureau of Education. It contains in its 1327 pages an abundance of information concerning all grades of American education, and parts of the educational systems of other countries. It is only possible here to refer to a few of its contents. Dr. Charles F. Thwing, president of Western Reserve University, contributes a chapter on the development of American universities, their organisation, conduct, and relations to the life of the nation. The chapter shows that the growth of university endowment funds has kept pace in the United States with that of the wealth of the country at large. For example, the productive funds of Yale College have increased from about 6000*l.* in 1830 to more than 1,000,000*l.* at the present time. The growth of libraries also has been significant in particular instances, yet Dr. Thwing says the "libraries of most colleges are inadequately furnished and inefficiently administered." The functions of universities in American communities are considered under various aspects. First, as conserving forces in the presence of a democracy inclined to make all things new; then as inspiring with high moral ideals an age inclined to pursue mere material aims. As an agency to promote systematic research—the seeking after truth as such—the university fulfils an increasingly useful function. It presents, as the chapter points out, materials for the study of all truth, in the world of nature and in the world of man. Another chapter of the report deals with education in France, and includes some interesting statistics concerning French universities. It appears that the registration in State universities has increased by about 60 per cent. since 1887, the total registration for 1901 being 29,931 students. The University of Paris greatly outnumbers all others in this respect, its total registration being 12,289 students. Lyons, with 2458 students, and Bordeaux, with 2119, stand next to Paris. As the distribution by faculties, law leads with 10,152 students, medicine follows with 8627, science comes third with 3910 students, and is closely followed by the faculties of letters with 3723 students.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 30.—"The Theory of Photographic Processes, Part ii. On the Chemical Dynamics of Development, including the Microscopy of the Image." By S. E. **Sheppard** and C. E. K. **Mees**. Communicated by Sir William Ramsay, K.C.B., F.R.S.

This paper forms a continuation of a preceding one on the kinetics of development (*Proc.*, lxxiv. pp. 447–473). By microscopical methods, the growth in the thickness of the reduced layer of silver particles, in their size and their number, under varying conditions of exposure and development, has been studied. For the structure of the developed negative the following facts were ascertained:—

(*a*) With constant development for a short time the depth of the image is independent of the exposure.

(*b*) With increased time the depth increases very rapidly at first, reaching a maximum for each exposure, after which it is constant, while the density of reduced silver still increases.

(*c*) With long development the depth increases somewhat with the exposure, a limit naturally being fixed by that of the film.

Size of the Grain.—This increases with the time of development, the *rate* being a function of the exposure, but the limiting size independent of this, and fixed by the original haloid grain. Thus in the early stages of development the size of the grain increases with exposure, but on ultimate development is independent of it.

Soluble bromides at moderate concentration give a smaller grain for the same time of development, but depending on the exposure. On ultimate development the size becomes the same.

Number of Grains Reduced.—In the surface-area the number is independent of the exposure, but in the volume unit for moderately long development the number increases with the exposure, and is nearly proportional to the density. It increases rapidly with the time of development, more so than the density, and soon reaches a maximum.

When plates are exposed through the glass side, the thickness of the reduced layer is much the same, but the numbers less. Further, the grains nearer the glass are larger, showing that the more exposed grains start development first. Generally, each grain develops as an isolated system, only uniting to form "aggregates" when the packing is close, as in high exposures. The true reaction-layer is in the gelatin skin surrounding the grain, its thickness being of the order 0·0005 mm., and the reaction is similar to the catalysis of H_2O_2 by colloidal metals, with convection excluded.

Early Stages of Development.—From considerations of the order of reactions the validity of the Watkins factorial method of development is discussed, and the "time of appearance" shown to be a measure of the development-velocity for the initial stage of development. For ferrous oxalate this initial velocity is shown to be proportional to the concentration.

Effect of temperature for ferrous oxalate can be represented by the formula of van 't Hoff, $\log K = -A/T + C$, but the temperature-coefficient for 10°, $K+10^\circ/K$, varies for different developers and emulsions, and cannot serve as a criterion for distinguishing rate of chemical action from diffusion in development.

It is further shown that "tanning" the film with formalin does not alter the development-velocity.

For the "penetration" of the developer, it was found that with plates exposed from the back the image appeared on the glass or film side first according to the exposure. This is explained by consideration of the micro-structure of the exposed film, and the conclusion is again obtained that the "re-activity" or readiness to start development of the individual grain is a steady function of the exposure.

From the absolute "time of appearance" of the image at the back it is concluded that the diffusion-induction is not great, especially since other considerations show that in the early stages of development the chemical reaction has more influence than diffusion.

Chemical Society, May 17.—Prof. R. Meldola, F.R.S., president, in the chair.—The desmotropic form of substances of the ethyl acetoacetate type in the homogeneous state and dissolved in neutral media: J. W. **Brühl** and H. **Schröder**. The authors claim to have established by optical measurements with solutions in various media that both the ethyl acetoacetates and their secondary and tertiary alkyl derivatives, and also the camphorcarboxylic esters and their alkyl derivatives, display a pure uniform ketonic structure, and are free from the enolic forms.—The chlorination of methyl derivatives of pyridine, part i., 2-methylpyridine: W. J. **Sell**. The compound C_6HCl_6N was obtained by chlorinating 2-methylpyridine in hydrochloric acid solution.—The absorption spectra of uric acid, murexide, and the ureides, in relation to colour and their chemical structure: W. N. **Hartley**. The ureides, diureides, and some oxypurin derivatives are divided by the characters of their absorption spectra into two groups, the oximino-ketones with no ethylenic linking associated with the carbonyl groups, and the substances which have one or more such linkings.—Observations on chemical structure and physical properties associated with the theory of colour: W. N. **Hartley**. The main feature in a coloured substance is the occurrence in two parts of the molecule of ethylenic and benzenoid groupings and of ketonic groupings. The explanation of colour, based on the change from a double linking (ketonic) to a single linking (enolic), should, if sound, be capable of explaining the occurrence of six bands in the spectrum of benzene, four in that of naphthalene, and four in that of anthracene. It is shown how this is possible from Kekulé's formula for benzene, and how this formula may be reconciled with the "centric" formula.—Further studies on dihydroxymaleic acid: H. J. H. **Fenton**. This paper describes the results of a study of the condensation of the acid with ammonia, and the behaviour of the acid and its esters towards various hydrazines.—The influence of light on diazo-reactions, preliminary notice: K. J. P. **Orton** and J. E. **Coates**, and (in part) F. **Burdett**.—Behaviour of solutions of propyl alcohol towards semi-permeable membranes: A. **Findlay** and F. C. **Short**. Some years ago Pickering stated that when a porous pot containing a 57 per cent. aqueous solution of propyl alcohol was immersed in either pure water or pure propyl alcohol, the water or the alcohol passed inwards to the solution. The authors have been unable to confirm Pickering's experiments, and suggest that the behaviour observed by him might be temporary and due to differences in the velocity of the diffusion of the pure liquids and the solution.—The thermal decomposition of formaldehyde and acetaldehyde: W. A. **Bone** and H. L. **Smith**. Formaldehyde decomposes at all temperatures between 400° and 1125° in accordance with the equation $CH_2O = CO + H_2$, and acetaldehyde at 400° in accordance with the equation $CH_3.CHO = CH_4 + CO$.—The synthesis of formaldehyde: D. L. **Chapman** and A. **Holt**, jun. The authors have succeeded in synthesising formaldehyde by maintaining a platinum wire at a high temperature in the following mixtures:—(*a*) carbon monoxide and hydrogen; (*b*) carbon monoxide, hydrogen, and steam; (*c*) carbon monoxide and steam; (*d*) carbon dioxide and hydrogen.—Oxymercuric perchlorates and the action of alcohol on mercury perchlorates: M. **Chikashigé**. Three new oxymercuric perchlorates are described.—The constitution of pilocarpine, part v., conversion of *iso*pilocarpine into pilocarpine: H. A. D. **Jowett**.

Royal Meteorological Society, May 17.—Capt D. Wilson-Barker, vice-president, in the chair.—Measurement of evaporation: R. **Strachan**. The author pointed out that the rainfall, evaporation, and percolation are related to each other, and that rainfall is commonly considered to form the sum of evaporation and percolation. If two of these quantities are found by experiment or observation, the other is assumed to be known. This, however, does not always hold good. A month may be very dry, and still evaporation will go on at the expense of previous percolation—and otherwise. A month may be excessively wet, then there may be another item to take into account, viz. overflow. As, unfortunately, it is not possible to make evaporation and percolation the subject of experi-

ment, except at a very few observatories, the author thinks it is desirable to be able to estimate, even empirically, the probable amounts of each. By using the meteorological data published for the Royal Observatory, Greenwich, he has calculated the probable evaporation for the year 1898, which agrees very closely with the observed evaporation at Camden Square and also at Croydon.—On a logarithmic slide-rule for reducing readings of the barometer to sea-level: J. **Ball.** This has been devised for the purpose of saving the time and labour usually occupied in working out the corrections from the international meteorological tables.

Royal Microscopical Society, May 17.—Dr. Dukinfield H. Scott, F.R.S., president, in the chair.—The movements of diatoms and other microscopic plants: D. D. **Jackson.** The author describes the observations and experiments made by him, some with artificial diatoms, which have led him to the conclusion that the movements referred to are caused by the escape of oxygen gas evolved in these organisms.

Faraday Society, May 18.—Dr F. Mollwo Perkin, treasurer, in the chair.—An application to electrolytes of the hydrate theory of solutions: Dr. T. Martin **Lowry.** The object of the paper is to consider the possibility of extending the hydrate theory to electrolytes in such a way as to take account of the observations which form the experimental basis of the theory of electrolytic dissociation. The hydrate theory postulates that an aqueous salt solution consists of a mixture of hydrates in equilibrium with the solvent and with one another. But it must be supposed that even in solution there is a limit to the possibility of hydrate formation, so that ultimately a stage will be reached at which the molecule as such will be unable to combine with any further quantity of water. The ionisation of an aqueous electrolyte consists essentially in a further process of hydration whereby the fully hydrated molecule combines with an additional quantity of water to form two or more hydrated ions. The hydration of the ions is thus conceived to be the primary cause of the ionisation of aqueous electrolytes. It is believed that this extension of the hydrate theory to the phenomena of electrolysis may help to remove the fundamental difficulty of Arrhenius's theory, namely, the absence of a motive for electrolytic dissociation.

Physical Society, May 26.—Meeting at the National Physical Laboratory by invitation of the director, Dr. Glazebrook.—The following special demonstrations were made:—The specific heat of iron at high temperatures: Dr. J. A. **Harker.** A knowledge of the specific heat of iron is important in the determination of high temperatures by calorimetric methods. Dr. Harker has determined the total heat of iron up to temperatures of 900° C. by heating the specimen in an electric furnace, the temperature of which was determined by a resistance thermometer, and dropping the iron into a water calorimeter. Dr. Harker also exhibited some new types of electric furnace for the attainment in absence of noxious gases of temperatures between 800° C. and 2200° C. The conductor conveying the electric current is a tube of solid electrolytes similar in composition to the filament of a Nernst lamp. An essential feature is that, for many purposes, the usefulness and life of a furnace constructed in this way may be much increased by adopting a "cascade" system of heating.—Apparatus for the measurement of small inductances: A. **Campbell.** The method of measurement is that adopted by Max Wien, and described by him in a paper on "Magnetisation by Alternating Currents" (*Wied. Ann.*, xiii., August, 1898). It is a modification of Maxwell's method of comparing two self-inductances, the source of voltage being alternating, and the indicating instrument a tuned optical telephone or vibration galvanometer.—Two new optical benches constructed for the laboratory by Messrs. R. and J. Beck: J. **Selby.** One of these is specially designed for the rapid testing of spherical and cylindrical lenses, such as are found in oculists' trial cases. The second bench is designed for the determination of the loss of light by absorption and reflection in telescopes and binoculars.

CAMBRIDGE.

Philosophical Society, May 1.—Prof. Liveing, vice-president, in the chair.—On the striation of the positive column in electric discharges: Prof. **Thomson.** The author considered the ionisation in a discharge tube by the collision of charged ions as well as of corpuscles against the molecules of a gas, and showed that if the pressure in the tube and the electric current through it had values situated between certain limits, there would be periodic alternations in the positive column analogous to striations.—On the calculation of the coefficient of re-combination of the ions and the size of the ions: Prof. **Thomson.** The re-combination of ions is due to oppositely charged ions attracting each other and forming a single system. When the ions are at a distance r apart the work required to separate them to an infinite distance is e^2/r, hence two ions starting from a distance r apart will not describe closed orbits about each other, *i.e.* will not combine if their kinetic energy is greater than e^2/r. Since the ions behave like the molecules of a gas, their kinetic energy will depend only upon the temperature, and can be calculated when that is known. If T is this kinetic energy, then for combination to take place e^2/r must be greater than T, or r less than e^2/T. Hence to find the number of re-combinations in any time, all we have to do is to find the number of pairs of ions which within that time get within a distance e^2/T of each other. This number, and hence the coefficient of re-combination, is easily calculated. If we assume that the ions in hydrogen are charged molecules of hydrogen, the coefficient of re-combination at 0° C. would be $1{\cdot}5\times10^{-6}$; the value found by experiment is about 10^{-6}, hence we conclude that the hydrogen ion is more complex than the hydrogen molecule. The kinetic energy due to temperature is shown to prevent the ions getting very much larger than the molecules; thus if the radius of the molecule were 10^{-8} cm., the radius of the ion could not exceed 3×10^{-8}.—Some physical properties of sodium vapour: P. V. **Bevan.** The experiments described in this paper were made to investigate the phenomena of the cloud of sodium vapour formed by heating a piece of metallic sodium *in vacuo* or in an atmosphere of hydrogen. In certain circumstances the sodium vapour forms a very sharply defined cloud with apparently a definite surface across which diffusion does not take place. The formation of this cloud, which was discovered by Prof. R. W. Wood, was found to be conditioned by the presence of water vapour in the atmosphere in which the sodium was heated. *In vacuo* the sodium vapour behaves like any other vapour, and in perfectly dry hydrogen there is no definite surface to the vapour observable when the sodium is heated. It was also shown that *in vacuo* the sodium begins to form vapour at the temperature of boiling water. The view is put forward that when the sodium cloud is seen on heating sodium in a vacuum tube the effect is due to the formation of an atmosphere of hydrogen occluded by the sodium and formed by the action of the sodium on sodium hydroxide.—A null method of measuring small ionisations: N. R. **Campbell.** Measurements have been made of spontaneous ionisations by adjusting the pressure of the air in a closed vessel containing a constant amount of uranium until the current through that vessel was equal and opposite to that through the spontaneously ionised gas. By this device certain difficulties connected with the measurement of capacity and the preservation of insulation are avoided.—The reflexion of sound at a paraboloid: Rev. H. J. **Sharpe.**

DUBLIN.

Royal Dublin Society, April 18.—Prof. J. A. McClelland in the chair.—Notes on the constitution of nitric acid and its hydrates: W. Noel **Hartley.** The author referred to a paper by him published in 1903 in the *Chem. Soc. Trans.* on the absorption spectra of nitric acid in various states of concentration. He had assigned the formula H_3NO_4 to normal nitric acid, and suggested that the several hydrates described were hydrates of this acid; but H. Erdmann, also in 1903, having isolated and described five nitric acids, the author was led to revise the formulæ of the hydrates in accordance with the constitution of these

compounds. The normal acid being pentabasic, $N(OH)_5$, there are several hydrates of this extending to

$$N(OH)_5.14H_2O.$$

Ordinary nitric acid of 1·42 sp. gr. consists entirely of the octobasic acid $(HO)_4N.O.N(OH)_4$, and the crystallisation of this was shown to the meeting by cooling the acid in liquid air.—The effect of very low temperature on moist seeds: John **Adams.** Seven species of moist seeds were submitted to the temperature of liquid air, with the result that they were all killed, while dry seeds were not adversely affected. The physiological processes involved were next considered, as well as the various theories put forward to account for death by freezing. An attempt was made to bring the results obtained into line with Macfadyen's experiments on bacteria, and the more recent investigations of Edwin J. Smith and Deane B. Swingle.—Injurious insects and other animals observed in Ireland during the year 1904: Prof. G. H. **Carpenter.** In this paper special attention is paid to Cecidomyiidæ, the pear-midge (*Diplosis pyrivora,* Riley) being recorded, and an account of *Rhabdophaga heterotia,* Loew., very destructive to osier beds in the county of Kilkenny, being given. Further instances are mentioned of Collembola injurious to plant roots and a new species of oribatid mite (*Lohmannia insignis,* Berlese) destructive to bean seedlings is described. The life-history of the well known mangold fly (*Pegomyia betae,* Curtis) is worked out in some detail.—Prof. **McClelland** made an addition to the communication he laid before the society at its February meeting.

EDINBURGH.

Royal Society, May 1.—Prof. Geikie in the chair.—The internal structure of *Sigillaria elegans* of Brongniart's "Histoire des Végétaux fossiles": R. **Kidston.** The primary xylon formed a continuous ring as in *S. elongata,* Bgt., described by Prof. Bertrand, but the protoxylon groups formed rounded projections, not pointed, as in *S. elongata.* The paper concluded with some general remarks on the development of the primary xylon of the Carboniferous lycopods, and the opinion was expressed that the solid stele was the most primitive type, followed by the continuous ring with a medulla, the series ending in that type of structure found in *S. spinulosa,* where the primary xylon assumes the form of a circle of isolated bundles.—The rainfall of the drainage area of the Talla reservoir: B. Hall **Blyth** and W. A. **Tait.** The observations had been carried out in connection with the new Edinburgh Water Works in order to obtain data for fixing an equitable compensation to the Tweed Salmon Fisheries Commissioners and other proprietors in the district. Seven gauges had been established at various levels, and observations had been taken continuously for seven years from 1896. The lowest gauge, at a height of 966 feet, gave an annual average of 61·43 inches, and the highest, at a height of 2627 feet, gave 65·53 inches, or only 0·41 per cent. per 100 feet rise. The greatest average was given by the gauge at the height of 1537 feet, the value being 73·92 inches. These facts showed that the rainfall was greatly affected by the exposure to prevailing winds and the character of these winds, quite apart from the effect of height. The extent of the drainage area was 6180 acres, and the average annual rainfall, as estimated from the observations, was nearly 14,600,000 gallons per day, of which one-third had to be given off as compensation.—The rainfall records in the Talla drainage area from 1896 to 1902: P. D. **Donald.** This contained further discussions of the records. The observations of rainfall were being continued by the Water Trust, and it was hoped that the information so gained would be of special value to all interested in water supply.—Variant forms of vanishing aggregates of minors of axisymmetric determinants: Prof. **Metzler.**

PARIS.

Academy of Sciences, May 29.—M. Troost in the chair.—The exact transmission of time by the telephone: E. **Guyou** (see p. 134).—On cyanocampho-acetic, cyanocampho-α-propionic, cyanocampho-α-butyric acids and their principal derivatives: A. **Haller** and A. **Couréménos.** The sodium derivative of cyanocamphor reacts with the methyl and ethyl esters of the α-monochlor- and monobromo fatty acids similarly to the alkyl iodides and bromides previously studied, the camphor derivative behaving as if it possessed the enolic form. These new compounds can be saponified by alcoholic potash, furnishing the corresponding acids, several esters, salts, and amides being described in detail.—The oscillations of locomotives under the action of various disturbing forces: Georges **Marié.** A study of the conditions under which the oscillations may accumulate to a dangerous amplitude, and of the means of avoiding these conditions in practice.—On the continued algebraical fractions of Laguerre: R. de Montessus **de Ballore.**—On partial differential equations of the elliptic type: S. **Bernstein.**—On the interpolation of continuous functions by polynomials: Martin **Krause.**—The electrolytic production of very fine wires: Henri **Abraham.** Starting with a fine drawn wire of a given material, the metal is removed electrolytically in a suitable bath, the resistance of the wire being measured during the experiment, the increase of the resistance giving an exact measure of the reduction of the diameter. For the production of uniform wires it is necessary that the electrolysis be conducted very slowly, and the method proved very successful for the purpose in view.—On tangential irradiation: A. **Guébhard.** A discussion of the mechanical and electrical theories as to the cause of photographic irradiation.—The examination of phosphorus sulphide for the presence of free white phosphorus: Léo **Vignon.** The Mitscherlich reaction (distillation with water) is useless for detecting free phosphorus in commercial phosphorus sulphide; the removal of the free phosphorus by heating in a current of hydrogen proved more serviceable.—On a reaction with discontinuous velocities of the green sulphate of chromium: Albert **Colson.**—On some physical properties of propane: Paul **Lebeau.** Pure propane was obtained from three sources, normal propyl iodide, isopropyl iodide, and isopropyl chloride, the final purification being effected in all three cases by fractional distillation of the liquefied gas. It remained liquid at the temperature of liquid air (−195°), boiled at −44°·5 C., and had a critical temperature of 97°·5 C., the critical pressure being 45 atmospheres. Propane is soluble in several reagents, its solubility being much greater than either methane or ethane. It is interesting to note that although propane does not solidify at −195° C., methane, its lower homologue, is crystalline at −184° C.—On methyl-acetyl-carbinol: André **Kling.** This acetol can be obtained by the oxidation of 2:3-butanediol by the action of the sorbose bacterium and by *Mycoderma aceti.* The resulting keto-alcohol is dextrorotatory, the oxidation proceeding at the expense of the lævo-form. The semicarbazone is well crystallised and readily isolated, and forms the best means of identifying this substance.—On the oxide of methoethenylbenzene: M. **Tiffenau.**—Syntheses in the anthracene series. The condensation of derivatives of benzodihydrofurfurane into γ-substituted anthracene derivatives: A. **Guyot** and J. **Catel.**—On methylnatalœmodine and natalœmodine: E. **Léger.** The name natalœmodine is given to a trioxymethyl-anthraquinone obtained by the action of sodium peroxide upon the aloin from Cape aloes. Details are given of its properties and the preparation of some of its derivatives.—On the acidity of some ethyl alcohols of commerce and on the variations in acidity at the ordinary temperature: René **Duchemin** and Jacques **Dourlen.** Alcohol slowly oxidises in the presence of air at the ordinary temperature, acetic acid being formed. The amount formed depends on the nature of the containing vessel.—The conductivity of colloidal solutions: J. **Duclaux.** A solution of a colloid can be filtered through a collodion film, crystalline substances passing readily through such a filter, the colloid remaining behind. It was found that the conductivity of the concentrated solution of the colloid was appreciably greater than that of the filtrate. From the results of the measurements it was calculated that the electric charge on each particle of colloidal ferric hydrate was about 1/500th of that corresponding to the gram-valence of an ion.—On the presence of noumeite in the detritic state in the neo-Caledonian Eocene: M. **Deprat.**—The wild coffee trees of French Guinea: A.

Chevalier.—On *Oïdium lactis* and the ripening of cream and cheese: J. **Arthaud-Berthet.**—On *Stearophora radicicola*, a fungus of the roots of the vine: L. **Mangin** and P. **Viala.**—The pathogenic action of *Stearophora radicicola* on animals: MM. **Charrin** and **Le Play.**—The phenomena of sexuality in the development of the Actinomyxides: M. **Caullery** and F. **Mesnil.**—The histological phenomena of asexual reproduction in Salmacina and Filograna: A. **Malaquin.**—Some variations in the coefficient of demineralisation in animals in a state of acid dyscrasia: A. **Desgrez** and Mlle. Bl. **Guende.**—The experimental reproduction of human cancer: M. **Mayet.**—On distemper in dogs: H. **Carré.**—On the geology of the Piedmont zone: Maurice **Lugeon** and Émile **Argand.**

DIARY OF SOCIETIES.

THURSDAY, JUNE 8.

ROYAL SOCIETY, at 4.30.—Researches on Explosives. Part III.: Sir Andrew Noble, Bart., K.C.B., F.R.S. (1) On the Thermoelectric Junction as a Means of Determining the Lowest Temperatures; (2) Studies with the Liquid Hydrogen and Air Calorimeters: Sir James Dewar, F.R.S.—Colours in Metal Glasses, and in Metallic Films and Metallic Solution: J. C. Maxwell Garnett.—On the Application of Statistical Mechanics to the General Dynamics of Matter and Ether. The General Method of Statistical Mechanics: J. H. Jeans.—On the Magnetic Qualities of some Alloys not containing Iron: Prof. J. A. Fleming, F.R.S., and R. A. Hadfield.—On the Phosphorescent Spectra of Sδ and Europium: Sir William Crookes, F.R.S.—On the Perturbations of the Bielid Meteors: Dr. A. M. W. Downing, F.R.S.—The Asymptotic Expansion of Integral Functions defined by Taylor's Series: Rev. E. W. Barnes.—Preliminary Note on Observations made with a Horizontal Pendulum in the Antarctic Regions: Prof. J. Milne, F.R.S.—Note Supplementary to a Paper "On the Radio-active Minerals": Hon. R. J. Strutt, F.R.S.—The Morphology of the Ungulate Placenta, particularly the Development of that Organ in the Sheep, and Notes upon the Placenta of the Elephant and Hyrax: R. Assheton.—A Preliminary Communication on the Life History of *Trypanosoma balbianii*: W. S. Perrin.—On the Effect of Carbon Dioxide on Geotropic Curvature of the Roots of *Pisum Sativum*: E. Drabble and Miss H. Lake.—The Pharmacology of Indaconitine and Bikhaconitine: Prof. J. T. Cash, F.R.S., and Prof. W. R. Dunstan, F.R.S.—Preliminary Note on the Occurrence of Microsporangia in Organic Connection with the Foliage of Lyginodendron: R. Kidston, F.R.S.—Chitin in the Carapace of *Pterygotus Osiliensis* from the Silurian of Oesel: Dr. Otto Rosenheim.—(1) The Synthesis of a Substance allied to Adrenalin; (2) On the Physiological Activity of Substances indirectly allied to Adrenalin: Dr. H. D. Dakin.

ROYAL INSTITUTION, at 5.—Electromagnetic Waves: Prof. J. A. Fleming, F.R.S.

MATHEMATICAL SOCIETY, at 5.30.—On a Class of Many-valued Functions Defined by a Definite Integral: G. H. Hardy.—On the Condition of Reducibility of any Group of Linear Substitutions: Prof. W. Burnside. On Criteria for the Finiteness of the Order of a Group of Linear Substitutions: Prof. W. Burnside.

FRIDAY, JUNE 9.

ROYAL INSTITUTION, at 9.—Submarine Navigation: Sir William White, K.C.B., F.R.S.

ROYAL ASTRONOMICAL SOCIETY, at 5.—The Meteors from Biela's Comet: W. F. Denning.—On the Formula for connecting Diameters of Photographic Images with Stellar Magnitude: H. H. Turner.—(1) The Moon's Observed Latitude, 1847–1901; (2) On the Discordant Values of the Principal Elliptic Coefficients in the Moon's Longitude: P. H. Cowell.—Determinations of Stellar Parallax from Photographs taken at the Cambridge Observatory. Introductory Paper: A. R. Hinks and H. N. Russell.—The Most Probable Position of a Point determined from the Intersections of Three Straight Lines: S. A. Saunder.—On the Relative Efficiency of Different Methods of Determining Longitudes on Jupiter: A. Stanley Williams.

SATURDAY, JUNE 10.

ROYAL INSTITUTION, at 3.—Exploration in the Philippines: A. H. Savage Landor.

WEDNESDAY, JUNE 14.

MINERALOGICAL SOCIETY, at 8.—The Chemical Composition of Lengenbachite: Dr. A. Hutchinson.—The Identity of the Ancient Amiantos of Cyprus with Chrysotile: Dr. J. W. Evans.—The Chemical Composition of Hutchinsonite: G. T. Prior.

CHEMICAL SOCIETY, at 5.30.—Influence of Various Sodium Salts on the Solubility of Sparingly Soluble Acids: J. C. Philip.—The Dielectric Constants of Phenols and their Ethers Dissolved in Benzene and *m*-Xylene: J. C. Philip and Miss D. Haynes.—Synthesis by Means of the Silent Electric Discharge: J. N. Collie.—The Ultra-violet Absorption Spectra of Benzene and Certain of the Mono-substituted Derivatives: E. C. C. Baly and J. N. Collie.—Association in Mixed Solvents: G. Barger.—The Ultra-violet Absorption Spectra of Derivatives of Benzene. Part II. The Phenols: E. C. C. Baly and Miss E. K. Ewbank.—The Action of Water on Diazo-salts. A Preliminary Note: J. C. Cain and J. M. Norman.—Synthesis of Substances Allied to Epinephrine: G. Barger and H. A. D. Jowett.—A Precise Method of Determining the Organic Nitrogen in Potable Waters: J. Campbell Brown.—Synthesis of 1:1-Dimethyl-Δ^3-tetrahydrobenzene: A. W. Crossley and Miss N. Renouf.—Bromine in Solutions of Potassium Bromide: F. P. Worley.

THURSDAY, JUNE 15.

LINNEAN SOCIETY, at 8.—Biscayan Plankton. Part VI. Colloid Radiolaria: Dr. R. N. Wolfenden.—Biscayan Plankton. Part VII. Mollusca: Dr. P. Pelsener.—(1) Longitudinal Nerves and Transverse Veins in Bamboos; (2) Some Indian Undershrubs: Sir D. Brandis, K.C.I.E., F.R.S.—Notes on a Skeleton of the Musk-duck, *Bizuria lobata*: W. P. Pycraft.—*Exhibitions*: *Arum maculatum*, in Relation to Insects (with lantern slides): Rev. J. Gerard, S.J.

FRIDAY, JUNE 16.

PHYSICAL SOCIETY, at 8.—On the Ratio between the Mean Spherical and Mean Horizontal Candle-power of Incandescent Lamps: Prof. J. A. Fleming, F.R.S.—The Electrical Conductivity of Flames: Dr. H. A. Wilson.—Contact with Dielectrics: R. Appleyard.—The Pendulum Accelerometer, an Instrument for the Direct Measurement and Recording of Acceleration: F. Lanchester.—A New Form of Pyknometer: N. V. Stanford.—Exhibition of a Refractometer: R. Appleyard.

MALACOLOGICAL SOCIETY, at 8.—Lecture on the Prosobranchiate Mollusca: J. E. S. Moore.—On the Extension of the Genus Macrochlamys to the Island of Mauritius: Lieut.-Col. H. H. Godwin-Austen.—Mollusca of the Porcupine Expeditions, Supplemental Notes, Part II.: E. R. Sykes.—On a Small Collection of Mollusca from Tierra del Fuego: E. A. Smith.—On two Miocene Gastropods from Roumania: R. Bullen Newton.—Revision of the New Zealand Patellidæ, with Descriptions of a New Species and Subspecies: Henry Suter.—The Conchological Writings of Captain Thomas Brown: C. Davies Sherborn.

THURSDAY, JUNE 15, 1905.

SOME RECENT BOOKS ON CELTIC.

Keltic Researches. By E. W. B. Nicholson. Pp. xviii+212. (Oxford: Clarendon Press; London: Henry Frowde, 1904.) Price 21s. net.

The Mythology of the British Islands. By Charles Squire. Pp. x+446. (London: Blackie and Son, Ltd., 1905.)

The Literature of the Celts, its History and Romance. By Magnus Maclean. Pp. xv+400. (London: Blackie and Son, Ltd., 1902.)

THOSE who have the study of Celtic at heart cannot but be rejoiced at the strides which it has made in recent years. At no period have the inhabitants of the Celtic countries—those of Wales and Ireland more especially—shown a keener interest in their languages and institutions than at the present day; the number of scholars engaged in Celtic research has never been so great; and this Celtic revival, so-called, is like to prove no passing outburst, fanned by eccentrics and sentimentalists; rather we should see in it the coming of the race into its own again, the reaping after many days of a rich harvest of literature and legend.

In the case of the Welsh, the movement has been partly the cause, partly the effect of the movement towards improved education, and is no longer of yesterday. It can be traced back some seventy years, to the founding of the British schools by the late Sir Hugh Owen. Thirty years later the same enlightened patriot added discussions, both learned and practical, on matters affecting the Principality, to the musical and literary contests at the Eisteddfod. About the same time the study of the Welsh language, which owed what life it had to the devoted labours of Chancellor Silvan Evans, received a fresh direction from the papers and speeches of Prof. Rhys, who inveighed against the school of Dr. Owen Pughe, and pointed the way to more scientific methods. The last fifty years have been marked by a steady, if gradual, advance; the interest in Wales and things Welsh, and the sense of nationality, have become ever keener and more real, the language has secured a fresh lease of life, and the study of philology and history has been, and continues to be, vigorous and fruitful; not the least happy augury for the future is the fact that a number of younger men, natives of the Principality, have already made a name in these fields.

Unlike the Welsh, by which it may have been in part suggested, the Irish revival is of comparatively recent date. It is none the less vigorous on that account. Within the last few years, owing largely to the efforts of the Gaelic League, Irish has been studied with eagerness by persons of every shade of opinion, and a determined attempt has been made to develop native industries. A society has been founded for the publication of Irish texts—it has already done considerable work—and a special school, the School of Irish Learning, has been started to give students a scientific training in the language and to open up the rich treasures of Irish literature. The necessary funds are provided in part by voluntary subscription, and the generous donor may hope that he is helping to raise up a race of scholars as devoted as O'Curry and O'Donovan, as distinguished as Stokes and O'Grady. Up to this present, there has been no corresponding movement among the Scotch Highlanders or the other Celtic peoples, but it will not be the fault of their congeners if their national aspirations remain unawakened. The Pan-Celtic Congress, which met for the first time in 1901, has for one of its aims to increase the feeling of union among "the sea-divided Gaels" themselves; it is attended by delegates from all the Celtic districts, as well from Brittany as from those on this side of the Channel.

Apart from the enthusiasm of the Celtic-speaking races for their own language and institutions, there is a growing tendency among the other inhabitants of these islands—themselves far from purely Teutonic—to recognise the importance of the Celtic element and to wish to be enlightened as to its history and literature. It is doubtless to meet this demand that there have appeared of late years a number of books on Celtic subjects, written not so much for the specialist as for the general public. Of the books at the head of this notice two—Mr. Squire's "Mythology" and Mr. Maclean's "Literature"—are of this more or less popular character. All three alike are the work of men whose distinctions are not confined to Celtic, and bear witness to the increasing interest which it is exciting among the British nation as a whole.

Mr. Nicholson's "Keltic Researches," as the subtitle indicates, are a series of studies in the history of the ancient Goidelic languages and peoples. The author's first object is to demonstrate to philologists certain unrecognised or imperfectly recognised linguistic facts; but, inasmuch as he has not made Celtic his one and only study, he does not write in a narrow, specialising spirit; his linguistic facts are important, but he values them chiefly for the light which they throw on history in general, on the Pictish question, on the Menapian settlements, and on the distribution of the Celtic languages in Britain and on the Continent. The main philological result of the book is to show that the loss of original *p*, a loss supposed to be the main characteristic of the Celtic languages, is of comparatively late date in the Goidelic group, that, in fact, *p* was kept at Bordeaux until the fifth century A.D. Those who wish to be satisfied as to the soundness of his linguistic foundation are advised to turn to the appendices, which make up a third of his book, immediately after reading the first eight pages.

We need scarcely point out that much of his matter is controversial, and that some of his conclusions are liable to be disputed. For instance, many will refuse to admit that the Picts spoke a tongue virtually identical with Gaelic; they will maintain with Stokes that they spoke something nearer akin to Welsh, or with Zimmer and Rhys that their language was not Aryan at all. On the other hand, there can be little doubt as to the correctness of his main linguistic results. Exception may be taken to the interpretation of his *pièces justificatives*, the Rom tablets and the Coligny calendar; but he is certainly right in inferring that, besides those of the Gallo-Brythonic branch, there existed in

Gaul a language or languages closely akin to Goidelic or ancient Gaelic of the British Isles. Strange to say, although every Celtist knows that the peoples of the Gallo-Brythonic group had *p* for *qu* from time immemorial—petor in Gaulish petorritum=Latin quatuor—and that those of the Goidelic branch retained *qu* like the Romans, the greater number have chosen to assume that Gaulish was co-extensive with Celtic on the Continent. In spite of the evidence of such names as Aquitania, Sequana, Sequani, it was the fashion to suppose that *qu* was unknown in Gaul and that all the Celts alike dropped the consonant *p* of the Indo-European parent speech, as, for instance, in Aremorica, Armorica, where *are* is approximately equivalent to the Greek παρά. In laying stress on the fact that the retention of the old *qu* and Indo-European *p* are characteristic of the Pictavian and Sequanian languages he has done valuable service to the cause of philology, and recalled Celtic scholars from a path of error. He does not, indeed, claim to be the first to point out that the Celtic languages of the Continent were not of one and the same type. He tells us that as early as 1847 Jacob Grimm showed that the charms in the work of Marcellus of Bordeaux were in a language virtually identical with old Irish, and that Pictet afterwards proved that Indo-European *p* was retained in one of these charms in the prefix *pro*. Half a century later (in February, 1891), in a paper read before the Philological Society, Prof. Rhys brought together certain *qu* names from the Continent to prove the same thesis, and proposed that the language in Gaul akin to Goidelic should be called Celtican. He insisted on the significance of the words of Sulpicius Severus in Dialog. I. 27, "Tu vero, inquit Postumianus, vel Celtice, aut si mavis, Gallice loquere, dummodo jam Martinum loquaris." So, too, Mr. Macbain, in the introduction to his etymological dictionary of the Gaelic Language (Inverness, 1896), inserts among the *q* group by the side of Goidelic "dialects in Spain and Gaul." This was not long before the Coligny calendar and the Rom inscriptions came to light, showing that the Sequani and the Pictones, at any rate, spoke languages belonging to the same group as old Irish.

There can be no question that the book deserves study. If it sometimes betrays inexperience—and the author would be the first to admit this—it shows signs of many-sided learning, and in some cases of rare insight; the whole breathes an impartiality and generous candour which are wanting in many searchers after truth.

"The Mythology of the British Islands," by Charles Squire, is an introduction to Celtic myth, legend, poetry, and romance. It is intended, as we have seen, not for the learned, but for the ordinary reader, and the subject is approached from the literary rather than from the scholastic standpoint. Believing that the classic fount from which the poet so long drew inspiration has lost its potency, that the Greek stories can no longer be handled save by the genius alone, the author has attempted to put the natives of these islands in possession of a new heritage of myth and tradition, a heritage which is as much their own as that of the Teutons and Scandinavians.

Although the Welsh mabinogi and romances, and much of the Gaelic saga, have been made accessible in translations, it is unlikely that the British public as a whole can have formed anything like an adequate idea of Celtic mythology. The works in point contain but few explanations, and he who opens them for the first time, while he may be sensible of their charm, cannot but be bewildered by the novelty of his surroundings. He feels that he has ventured into a new world, peopled by characters whose very names are, for the most part, unfamiliar. If he wishes to understand their setting, to trace the connection between them, he must peruse innumerable lectures and learned essays, a task which is like to prove no light one. Mr. Squire's book is calculated to meet his difficulty. In it he will at last be formally introduced to the personages of Celtic mythology, to the gods and giants of the Gaels, to the champions of the Red Branch of Ulster—heroes of an epic almost worthy to rank with that of Troy—and to Finn and his Fenians. He will also make acquaintance with the chief figures of the Brythonic Pantheon, with the earlier race of gods, and with Arthur and his knights, who will be seen to belong to the same company.

As our author does not claim to have written an original work, it goes without saying that we are not called upon to enter into a discussion of his subject-matter. He has studied the works of the best scholars, and for the most part he adheres to them faithfully. It is possible that in some cases he may show himself over positive, that he may be inclined to treat as certain what his authority has advanced as a conjecture. But since his sole object in writing is to gain a larger audience for the studies of others, slips of this kind cannot be regarded as serious.

In our opinion his book is both useful and attractive. His treatment of his subject is thorough and conscientious, and he has realised his hope of presenting it in a lucid and agreeable form. It will be matter for surprise if he does not inspire his readers with some at least of his own enthusiasm.

Of Mr. Maclean's "Celtic Literature" there is no need to say more than a few words. It is some time since it appeared, and we doubt not that many of the readers of this Journal are already well acquainted with it It is the first attempt to give in brief compass an account of Celtic literature from the earliest times to the present day. Like Mr. Squire's "Mythology," it is intended to serve as a popular introduction; at the same time, it aims at satisfying those in quest of information as to original sources and books of reference. From both points of view it has much to recommend it; it will leave the general reader with a clear idea of the main outlines of the subject, while the student will find in it a painstaking and, within certain limits, a trustworthy guide. We are inclined to prefer the chapters dealing with Celtic literature in modern times, with the Highland bards before the Forty-five, with the master gleaners of Gaelic poetry, &c. The pages which describe the influence of Celtic on English literature are also interesting reading. The book ends with a survey of Celtic studies and a list of Celtic scholars past and present.

WEATHER INFLUENCES.

Weather Influences: an Empirical Study of the Mental and Physiological Effects of Definite Meteorological Conditions. By Dr. E. G. Dexter. Pp. xxxi+286. (New York: The Macmillan Company; London: Macmillan and Co., Ltd.) Price 8s. 6d. net.

THE effect of changes of weather on human activities has been the subject of much discussion, and each of us has no doubt formed an opinion on how he individually is affected by different meteorological conditions. The problem as affecting the behaviour of humanity in the mass has, however, received but scant attention hitherto. The statistical method affords the means of obtaining numerical results which enable us to estimate the importance of such effects.

Meteorological statistics are nowadays available from most centres of population; social statistics are also plentiful, yet of these only a limited number can be made to yield information on the general conduct or the working capacity of the community as a whole. In the book before us Dr. Dexter has collected and discussed sixteen classes of data culled from school records, covering both questions of attendance and conduct, police records dealing with cases of assault, drunkenness, murder, suicide, arrests for insanity, discipline in penitentiaries and the health of the force, the death register, registers of attendance in the out-patient departments of hospitals, and records of the number of clerical errors discovered in the books of certain banking establishments. The latter are the only data studied which deal exclusively with mental activities. All the records refer to New York City or to Denver, Colorado. The meteorological statistics with which they have been compared were obtained from the U.S. Weather Bureau.

The effects of seasonal changes are first discussed, and then the influence of each of the meteorological elements is considered separately. The general method of arranging the material for this purpose will be clear from the following description of that of dealing with the connection between temperature and assault. The days falling within the period considered were arranged in groups according to their mean temperatures, each group extending over a range of 5° F. On the assumption that temperature has no effect on assault, the number of days in each group is proportional to the "expectancy" of assault for that group. The actual number of occurrences of assault on the days of the group is computed as a percentage of the "expectancy," and curves have been drawn using the "occurrences" as ordinates and temperatures as abscissæ.

In dealing with the element rainfall the usual meteorological distinction has been drawn between days of rainfall, on which 0·01 inch of rain or more was measured, and dry days. It seems a pity that a further subdivision was not made. Most of us would be inclined to draw a wide distinction between showery days with only a few hundredths of an inch of rainfall and days of steady downpour. Even if such a further subdivision had been adopted, days with a few heavy showers would not be distinguishable from days of continuous fall; probably a classification on the basis of duration rather than amount of rainfall would yield results which would repay the labour involved in tabulating the records of self-registering rain gauges.

The majority of the curves show fluctuations which are greatly in excess of any which could be due merely to accidental variations. The number of data is in some cases extremely large (about 40,000 cases of assault), and there can be no doubt about the genuineness of the effects of meteorological changes.

The interpretation of the results is, however, a matter of considerable difficulty, and the possible influence of other than meteorological causes has to be steadily borne in mind. The general line of argument adopted regards the curves as compound functions of "irritability" or "emotional state" and "available" or "reserve energy." Thus, to return to the temperature-assault curve, we find a marked deficiency of occurrences at low temperatures. This has been taken to mean that under these conditions so large a portion of the vital energy is used up in supporting normal metabolic processes that the surplus available for active disorder is small. Under warmer conditions our pugilist, in addition to being more out of doors and thus seeing more of his neighbour, has more reserve energy available for active warfare, and the work of the police is proportionately increased. Above 65° the curve commences to rise with increased rapidity. Fighting energy is now at its prime, and at the same time "irritability" or quarrelsomeness is rapidly increasing. The temperature group 80°–85° shows a conspicuous maximum in the relative frequency of assaults. In the next group, 85°–90°, the curve exhibits a sudden drop. Irritability may very possibly be at a maximum, but the energy necessary to commence war is lacking, and a mere desire to fight is not a punishable offence. It is an interesting fact that the curve for women shows the above effects even more conspicuously than the one for men. A similar accentuation of the general characteristics is shown in all cases in which the number of data is sufficiently large to justify a separation of the sexes, so that it would appear that women are, on the whole, more susceptible to weather influences than men.

Some of the most interesting and at the same time most inexplicable curves are those which show the effect of the height of the barometer on human activities. With a few exceptions all classes of data show a marked excess of occurrences for periods of low barometer and a corresponding deficiency when readings are high. We cannot set this down to the direct effects of the diminution of pressure on the human organism; crime, &c., does not increase with altitude. Attempts at explanation by calling to our aid the usual accompaniments of a low barometer, viz. wind, rain, or cloud also fail, for when the effects of these elements are considered separately we find that in a number of cases the results contradict the hypothesis. Dr. Dexter directs attention to the peculiar "feel" which some people have for the approach of a storm, but this hardly amounts to an

explanation. It has been suggested that the radio-active emanation which is always present in the atmosphere in varying quantities may not be without influence on the human organism, and if, as Elster and Geitel suppose, this emanation is mainly derived from the underground air, which is more copiously discharged into the atmosphere as pressure decreases, it may be possible to establish a connection between the "storm feel" and the presence of radio-active emanation. If this be so we should expect to find the effect more pronounced with a falling than with a rising barometer, and, in the absence of direct measurements of the amount of emanation, the results obtained from a classification of the days, or perhaps better still, by a subdivision of the data used in constructing the present curves, on this principle would probably be interesting. Such a separation might prove profitable from a purely meteorological point of view, apart from all considerations of emanations, radio-active or otherwise. Possibly the peculiar abnormalities shown by most of the data for days of calm may be to some extent due to similar causes. The connection is, however, a very complicated one; attempts to trace a similarity between days of calm and days of low barometer fail signally.

We cannot here enter into a discussion of all the results or criticise the individual conclusions arrived at. In the final chapter Dr. Dexter further develops his thesis of the "available energy" and "emotional state" in the light of all the accumulated evidence, and comes to the conclusion that the effect of weather changes is greater on the former than on the latter, at any rate in its practical effects on conduct.

The study of the problems dealt with in the book is not without a certain practical interest to all who are responsible for the control of large numbers of individuals. If certain meteorological conditions can be shown to have a deleterious or beneficent influence on conduct or working capacity, it is well that we should recognise the fact as clearly as possible, and do what we can to mitigate the harmful conditions. Man cannot hope to control the weather, but he can modify the highly artificial conditions under which he lives to a very large extent.

A LIMNOLOGICAL MONOGRAPH.

Le Leman, Monographie Limnologique. By Prof. F. A. Forel. Vol. iii. Part ii. Pp. 410–715. (Lausanne: F. Rouge et Cie., 1904.)

IN the issue of this, the second part of his third volume, Prof. Forel completes his great monographic study of the Lake of Geneva. The veteran pioneer of scientific limnological research is to be congratulated on the successful termination of his monumental task, commenced some half-century ago.

The impetus which the study of lakes has received from the labours of Forel has now carried us so far that we find it difficult to realise the arduous nature of the work accomplished by him, who had in so many different directions to make the first tentative trials of methods of research with which all students of limnology are now familiar. The completed work is not merely a compendious study of the Lake of Geneva, but is besides of the utmost value as a general study of the nature of fresh-water lakes. In his painstaking study of this one lake he has been so fortunate as to observe and explain in a satisfactory manner many phenomena of general scientific interest and importance, among others the mysterious rise and fall of the waters of the lakes now known as seiches, the peculiar abyssal fauna of the lake, &c.

The present part of the work, which is mainly historical, deals with such varied subjects that it is difficult to particularise. Nothing having the slightest connection, direct or indirect, with the Lake of Geneva is destitute of interest for Prof. Forel, and we find here discussed many questions which a less enthusiastic limnologist might have been content to leave to students of other departments of knowledge. He gives a *résumé* of the history of the surrounding countries, of legislation, the fluctuations of population, local traditions, &c. More particularly apposite to the subject are the history of the lake dwellings, undertaken fifty years ago, in company with a band of archæologists of which he laments that he is the only survivor, the history of navigation, of fishing, and of pisciculture.

The history of navigation is treated very fully, from the canoe of the lake dweller to the modern steamer, and is illustrated with reproductions of many ancient pictures of ships; with such fulness of detail is the subject treated that we have a list of steamers plying on the lake from the *Guillaume-Tell* of 1823 to those of the present day.

The ancient tradition of the "éboulement du Lauredunum" is discussed in its scientific bearings. The tradition, supported by contemporary chronicles, is that in the year 563 A.D. a mountain was precipitated into the lake, destroying a castle, villages and churches, causing a flooding of the shores of the lake, and much destruction of property and life in Geneva. He shows that a landslip, such as has occurred several times in history, could not account for the production of great floods. Although he has abandoned the belief that earth movements habitually produce seiches, he admits that a great earthquake might be the cause of the land-slide, and coincidently of a great seiche, which would cause destruction on the shores of the lake. He thinks it more probable, however, that at a time of ordinary flood, when the waters of the lake were very high, an ordinary seiche of no more than a metre of amplitude might cause considerable flooding in Geneva, and perhaps wash away some wooden bridges and houses, the connection with the landslip being a mere coincidence.

In his philosophical reflections at the conclusion of his work, Prof. Forel claims that there have been few problems presented to him in the course of his investigations which he has not been able to solve, and the more difficult of these few are general problems, not belonging to his special province, and the solution of which must be sought in other lakes. He would, however, guard against this assertion being misunderstood as a boastfully complacent assumption that he has exhausted the subject. Every naturalist has his limits, determined from within by the extent of his powers, from without by the state of the

sciences in the age in which he lives. What is accomplished in one generation is the foundation for the achievements of the next.

That the subject is not exhausted we may easily see by remarking the progress that has been made in one of its departments most easily reviewed, since Prof. Forel finished that part of his work. In biology, even in the simple cataloguing of the lacustrine animals and plants, it is obvious that the work accomplished under his guidance is no more than a beginning in this direction, and specialists in any branch find abundance still to do. It is with no intention of belittling the work of Prof. Forel that this aspect of the subject is adverted to. It is a great work patiently carried through, and will serve as a foundation for all future limnological studies.

HENRY SIDGWICK'S ESSAYS.

Miscellaneous Essays and Addresses. By Henry Sidgwick. Pp. vii+371. (London: Macmillan and Co., Ltd., 1904.) Price 10*s*. net.

IN this volume we have the first instalment of the shorter essays of that brilliant thinker, Henry Sidgwick. They have been chiefly collected from journals and reviews, but two are now published for the first time. His philosophical lectures and papers are reserved for a companion volume. In a way, the selection of articles now before us illustrates a period of thirty-six years of the life of one of the most striking personalities of our time, and on that account, and from their breadth of view, they have a value even though the occasion of their appearance is long past.

Of the sixteen papers, six are literary or critical, six deal with questions of socialism and economics, and four with education and university affairs. We were surprised and somewhat disappointed to find no reminiscence of his activity in connection with the education of Englishwomen, but perhaps more may be expected when the histories of Newnham and Girton come to be written.

A detailed review of the essays on Shakespeare, Matthew Arnold, and Clough, or of those on political economy or sociology, hardly falls within the sphere of this Journal, but few of our readers who are interested in the burning question of the best education for men of science will regret having read Sidgwick's essay on "The Theory of Classical Education," reprinted from F. W. Farrar's "Essays on a Liberal Education," which was originally published in 1867. In the light of the recent controversy on the Greek question much of this excellent paper reads as if it had been written yesterday, and it is difficult to avoid the reflection that if several of the writers of controversial letters to the *Times* had read this essay of forty years ago, both their matter and manner might have been improved.

With respect to the classical element in a scientific education, Sidgwick was of opinion that although science had at length broken its connection with what was so long the learned language of Europe, yet everyone who aspires to become a "learned" man of science will require to read Latin with ease, but that the sole stock-in-trade of Greek necessary for him would be a list of words that he could learn in a day and the use of a dictionary that he might acquire in a week. In other words, he appeared to be in favour of the retention for the highest class of science students of that modicum of Greek which is at present compulsory at Oxford and Cambridge, only he would perhaps have liked to see it reduced and treated as a distinct part of the direct teaching of English.

A clear distinction is drawn between natural and artificial educations, and between the effects of literary and of scientific training. With regard to the latter Cuvier's famous remark is quoted with approbation:—

"Every discussion which supposes a classification of facts . . . is performed after the same manner; and he who has cultivated this science merely for amusement, is surprised at the facilities it affords for disentangling all kinds of affairs."

He admits that a student of languages could not honestly claim an analogous advantage for his own pursuit. The editors are justified in the inclusion of the essay on "Idle Fellowships" in spite of the fact that the evils of which it complains have greatly diminished. The general educational considerations discussed are of so wide a bearing that they are not less true now than in 1876, when the essay was published.

We feel certain that those who peruse this volume will share our gratitude to the editors for their share in the re-publication.

OUR BOOK SHELF.

The Insulation of Electric Machines. By H. W. Turner and H. M. Hobart. Pp. xvi+297. (London: Whittaker and Co., 1905.) Price 10*s*. 6*d*. net.

THE perfecting of the modern dynamo electric machine, and the necessity of high potential differences have within recent years quite altered our ideas about insulation. Electrical engineers have come to view the subject from a different standpoint on account of the importance of disruptive strength of the material apart from conduction pure and simple. The book under review appears at a very appropriate time. Our knowledge of the physical properties of insulators is now sufficient, and the want of a really good book on the subject is great enough to justify its appearance. It will be welcomed by the electrical engineer as a most valuable addition to his library.

The book opens with an account of the requisites for insulating materials, and the most perplexing phenomena met with during the testing of the same. Why is it that air has comparatively such low dielectric strength, and yet it is a very good insulator as ordinarily understood? Again, why does the apparent dielectric strength per unit thickness of such a substance as mica vary with the thickness? These and many other matters difficult to understand are laid before the reader. The properties of insulating materials and the influences of temperature and moisture upon them are next dealt with. The authors quite rightly lay stress upon the testing of insulators at, or even exceeding, their working limits of temperature, and the futility of baking to obtain temporary insulation unless moisture be permanently excluded. When dealing with the influence of brush discharge mention might with advantage have been made of the production of nitric acid, and the ultimate

breaking down of the insulation. The production of ozone—the forerunner of the above effect—is a matter of the utmost importance to electrical engineers, especially in damp climates.

That portion of the book dealing with varnishes is most valuable. The pros and cons. of the use of linseed oil, which undoubtedly has a very extended use at the present time, and other acid bodies are well set forth, as are those of the use of insulators of paraffin origin. The uses to which oils can be put as insulators, their various characteristics, their purity and methods for purifying and drying are carefully dealt with. Presspahn-mica is advocated instead of micanite for high tension working.

An important part of the work is that which deals with insulation of armatures, field-coils, and transformers. It is well shown upon what the so-called "space-factor," that is the ratio of area of copper to gross area of slot, depends. Very valuable suggestions are made with regard to pressure tests. Long time high pressure tests are likely to injure apparatus, and are not recommended—a few seconds' application is sufficient. The appliances in use for taping and handling insulation material, and a most interesting description of the tools employed, together with a useful bibliography, close what is really a valuable book. The printing is good, and the illustrations are excellent. ERNEST WILSON.

Insect Life. A Short Account of the Classification and Habits of Insects. By Fred. V. Theobald, M.A. With numerous illustrations (53 in the text). Second edition, revised. Pp. xi+235. (London: Methuen and Co., 1905.) Price 2*s.* 6*d.*

THE first edition of this work was published in 1896, and the public interest in entomology is evidenced by the increasing number of books on the subject which reach a second edition within a comparatively short time of publication. A cheap popular illustrated book on insects seems at present to be assured of a sale at least sufficient to cover expenses, which was not the case a few years ago.

The second edition is exactly similar to the first as regards its size, illustrations, and general contents; but here and there we notice occasional additions. There is much useful information in the book, but we regret that the second edition has not been more carefully revised, for, apart from occasional misprints, several erroneous or obsolete statements contained in the first edition have been repeated in the second. Thus on p. 3 (note) we read, "The total number [of insects] described, however, is under 250,000." This is probably based on Kirby's estimate in his "Text-book of Entomology" (1885) of 222,000; but the later estimate given in the second edition (1892) was 270,000, which would require to be augmented by many thousands to be correct for 1905. On p. 87, "The so-called Apples of Sodom found near the Red Sea," should, of course, be the Dead Sea. While it is true, as stated on p. 105, that *Danaus chrysippus* is the only European species of the genus, the much larger insect occasionally found in England is the common North American *D. erippus* (or *D. archippus*), introduced, but which may not improbably become naturalised in Europe, and has established itself within the last half-century in many of the Pacific Islands, as well as in Australia and New Zealand. Lastly (p. 166), it is possible that the bite of the species of tsetse fly which destroys cattle in South Africa may be "comparatively harmless to man"; yet, as Mr. Theobald must certainly know, the terrible sleeping sickness of Western and Central Africa is now ascribed to the bites of different species of tsetse flies infesting those regions.

We hope that when this little book reaches a third edition Mr. Theobald may have an opportunity of enlarging it, for entomology, like other sciences, advances so rapidly that it is not possible to bring it up to date, unless the author gives himself a free hand in this direction.

The Radial Area-Scale. Patented by R. W. K. Edwards. (Richmond, Surrey: Morgan and Kidd.) Price 3*s.* 6*d.*

THIS ingenious instrument is designed for use in finding the approximate areas of irregular plane figures such as indicator diagrams. It consists of a sheet of transparent celluloid marked with eleven scales on lines radiating from a point at equal angular intervals of about 3°, and so divided that a scale reading is proportional to the area of a sector from the centre up to that point. When used, the sheet is laid over the figure to be measured, and is adjusted until the figure is just contained within the bounding radials, with its outline cutting the nine inner scales each in two points. The outer and inner readings at these points are now taken and the two sets added; the difference between the two sums gives the required area. The entire operation occupies about three minutes. Applied by the writer to a 3″ circle and a 6″ semicircle, the results were correct in both cases to within $\frac{1}{4}$ per cent. As the outside radials include an angle of about 30°, the instrument is quite quickly adjusted over large or small figures of any shape, and the scales are clear and easy to read. To ensure a good approximation, Simpson's rule has been cleverly applied in figuring the scales. The instrument seems likely to be of considerable service, and should be widely known.

A Preparatory Course in Geometry. By W. P. Workman and A. G. Cracknell. Pp. viii+56. (London: W. B. Clive, 1905.) Price 9*d.*

THE little book by Messrs. Workman and Cracknell is preparatory to a forthcoming work on "Geometry, Theoretical and Practical," on which the authors are now busily engaged. It consists essentially of a set of exercises on the accurate scale drawing of lines, angles, triangles, and polygons, and requires the reading off of quantitative results as regards lengths and angles. Areas, ratios, and the general properties of circles are not reached in this volume. It trains the youth in the proper use of the drawing-pencil, straight-edge, scale, protractor, set-square, and compass, and gives him a concrete knowledge of, and practical insight into, geometrical truths as a preliminary to more formal work. Teachers using the book would do well when valuing class work to act on a suggestion contained therein, and give varying credit according to the degree of accuracy disclosed by the results. The book gives good promise of another very interesting class book of elementary geometry.

The Evolution of the World and of Man. By George E. Boxall. Pp. xi+191. (London: T. Fisher Unwin, 1905.) Price 5*s.*

A SINGLE example to show how Mr. Boxall proposes to supplement the deficiencies in the story of evolution as told by science will enable possible readers to estimate the value of his book. On p. 30, after stating that geology tells us the order in which various strata were laid down, he continues:—"but no attempt has as yet been made to estimate the temperature, for instance, when the granite was first deposited, and yet this should not be a difficult problem to solve. Thus, of the true metals, aluminium is the only one which appears in the granite, . . ." and the account continues with the same disregard of scientific fact. Mr. Boxall expresses his own view of the value of the book by not troubling to provide an index to it.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Possibility of Reducing Mosquitoes.

IN his able review of James and Liston's interesting "Monograph of the Anopheles Mosquitoes of India," published in your issue of May 25, Dr. Stephens recapitulates the arguments of these authors in favour of their hypothesis that "the task of materially reducing the number of Anopheles in any place will undoubtedly be one of great magnitude." As the subject is one of the greatest sanitary importance, it may perhaps be advisable to add that the validity of these arguments is by no means accepted by all students of the subject. They are based for the most part on the results of some anti-mosquito work done at Mian Mir by Dr. Christophers and Captain James. Perhaps those of your readers who are not medical men may not be cognisant of the fact that an exhaustive and, I think, destructive criticism of this work has been published by Colonels Crombie and Giles, Captain Sewell, and myself—*vide British Medical Journal*, September 17, 1904, and *Journal of Tropical Medicine*, 1904. My own conclusions were that the operations cost too little to be effective, and that no exact method was employed for enumerating the numbers of mosquitoes present before and after their commencement. So far as I am aware, Dr. Christophers and Captain James have not replied to our criticisms, and I therefore feel justified in assuming that the case has gone against them by default. I should add that I hear on very good authority that the operations at Mian Mir are now being continued on a better basis.

The principal argument of our authors appears to be that the local reduction of mosquitoes will be wholly or largely impracticable because of immigration of the insects from outside. Thus they mention four methods by which Anopheles are dispersed, namely, by flight, by streams, by carriages, and by gradual spreading in all directions "by short stages," and think that the last method is "overlooked by those who have no intimate knowledge of mosquito habits, but who readily draw up schemes for their wholesale destruction." I fear that these very self-evident facts were well known and carefully considered long before the authors commenced their researches, and, moreover, that they do not by any means establish their case. It is quite obvious that a considerable number of mosquitoes must always find their way by diffusion into any area of operations; but this is not enough. What the sceptics have to prove is that the number of immigrants must be so large as nearly, or completely, to compensate for the local destruction. This is quite a different proposition, and one which will, I think, tax their ingenuity to maintain. If the local mosquito-density is to remain the same in spite of local destruction, it can only be by means of an abnormally large compensatory immigration setting in coincidentally with the commencement of the work of reduction. But what is there to determine such an extraordinary and suicidal influx? Mosquitoes do not, like a gas, exist under a pressure which compels them to fill up a vacuum, and we can scarcely suppose that they voluntarily move in the direction of their own destruction. But, even if they do rush in to fill the local vacuum, they must, in order to do so, forsake the outlying tracts of country (which will be correspondingly benefited by their absence), so that the total average reduction over the whole area influenced by the operations will be exactly the same whether migration takes place or not—an argument which appears to have been overlooked by the sceptics.

Owing to the fact that the to and fro movements of all random wandering must tend to annul each other—that is, that the vectorial sum of such movements must tend to zero—I think that migration is not likely seriously to counteract the effect of anti-propagation measures. I should like to refer those interested in this part of the subject to a paper by me, published in the *British Medical Journal* for May 13, in which I have endeavoured to approach the subject analytically. My results agree with those of the late Mr. Ronald Hudson, who kindly commenced a similar analysis for me shortly before his lamented death, and also, I may add, with general experience, which shows that though a few mosquitoes may occasionally wander to considerable distances, the large bulk of them remain near their breeding pools. I venture to think that those who would prove the converse must do so, not by citing individual cases of long wandering, but by making a much more exact numerical determination of the amount of immigration than they have yet attempted, and by showing that it greatly exceeds the local birth-rate—a somewhat difficult task. That their observations are not always those of others may be seen from the following quotation from Dr. Malcolm Watson's report on the highly successful anti-malaria measures carried out in the Federated Malay States (*Journal of Tropical Medicine*, April 1, p. 104):—"A definite improvement in the health of Klang was evident when only the swamps nearest to the main groups of houses had been dealt with, and while other swamps within the town were still untouched. The mosquitoes from these did not appear to travel any distance, and there has been no evidence of dangerous immigration of Anophelines from the extensive breeding places which until the middle of 1904 existed just outside the town boundary, and some of which still remain."

So far as I can see, the case must be the same for mosquitoes as for most other organisms, including man. We should be very much surprised if anyone were to maintain that the population of the British Isles, for instance, would remain the same after abolition of the birth-rate. Why, then, should we assume such a proposition for mosquitoes? RONALD ROSS.

The Romance of the Nitrogen Atom.

THE letter of Dr. F. J. Allen (NATURE, May 4) on the critical temperature of living substances has interested me immensely. The ideas contained in it have often presented themselves to me in a crude way, and I hope Mr. Allen will find opportunity for elaborating them. I have often thought, when pondering over what one may venture to call the *versatility* of nitrogen, that a useful book might be written on the chemistry of the nitrogen compounds, including the mineral and organic compounds of that element in one view. If it did no other service it would help to save the mind of the chemical student from being enslaved by the phrase, "the chemistry of the carbon compounds." If the phrase "Ohne Phosphor kein Gedanke" is true, may we not with equal truth say "Ohne Stickstoff kein Leben"? The marvellous powers stored in the carbon atom are sufficiently *en evidence* in chemical science; yet may we not recognise the nitrogen atom as the magic "demon" (borrowing a figurative term from Clerk Maxwell) that holds the wand, that (under given conditions such as are noted by Dr. Allen) turns the atoms of oxygen and hydrogen hither and thither in the multiplex atomic relations of growth and metabolism in the living organism, and especially in that little understood complex we call chlorophyll? We know that the inert N_2 molecule of the atmosphere is made up of atoms which, in the nascent state, are possessed of great chemical energy, and we may fairly, I think, explain the inertness of ordinary atmospheric nitrogen by the stability of its molecule (N_2) as arising out of a difference in the ionic constitution of the two atoms which form the molecule. Is it not here that we may seek for the explanation of the otherwise puzzling fact that in the extremely stable compound NH_3 the nitrogen atom is trivalent, while in the oxides, halides, &c., it is pentavalent? The action of the nitrogen atom, in the way suggested by Dr. Allen, is illustrated by the well known necessity in the fertilisation of soils for the conversion of NH_3 into nitrates of alkaline bases, in order that the nitrogen in a *more unstable state of combination* may do its special work in the internal economy of the plant. I recollect discussing this matter some years ago with Dr. Voelcker, when I had the pleasure of meeting him at an agricultural gathering in this neighbourhood. The modern idea of ionisation of atoms seems also to throw light upon the fact that N_2

and H_2 combine to form NH_3 under the influence of the silent electric discharge, while at the temperature of the spark-discharge NH_3 is again split up into N_2 and H_2. The running down also of HNO_3 through the whole series of oxides into ammonia in the Grove cell is full of interest from this point of view, and the subject, with its manifold ramifications, is a fascinating theme for a thesis.

Bishop's Stortford, May 30. A. IRVING.

An Inverted Slab in a Cromlech.

THE remarkable articles on Stonehenge and other monuments by Sir Norman Lockyer have naturally stimulated reflection upon all that concerns megalithic remains, and therefore, perhaps, the following curious circumstances may be of some interest.

At Henblâs, in Anglesey, is a cromlech, or rather, I suppose, a dolmen, of remarkably rude and massive aspect. Two uprights remain, the larger of which is about 15 feet high by 9 feet thick, and both are very rough and irregular in shape. Resting against these, at an angle of about 20° or rather less from the horizontal, is a thinner stone, about 3 feet thick and some 13 feet square, presumably a top-stone. All are of a hard quartzite, which occurs among the schistose rocks of the district. No good exposure of this is known within a mile or so of the cromlech (a fact which Captain Evans, of Henblâs, informs me was pointed out to him long ago by Sir Andrew Ramsay). But at the base of the uprights are some obscure exposures that appear to me to be *in situ*, and I am inclined to think, therefore, that the materials were obtained on the spot.

Now the supposed top-stone is rough, like the uprights, on its upper surface, but its under-side is beautifully and finely ice-worn! It is clear, therefore (for it is certainly not a boulder), that it has been turned upside down.

Further, not only is it ice-worn, but the *direction* of the ice-movement can be made out, there being distinct lee-sides to its finely striated bosses, and these lee-sides look to N.N.E. But the natural direction of glaciation in the district is to S.S.W. Therefore, the stone has not only been turned upside down, but turned round as well.

If the materials were brought from some distance, these facts are, of course, of less interest. But if, as I think much more probable, they were obtained on the spot, it is clear that they throw a little light upon the proceedings of the builders in their work of lifting these great stones.

Achnashcan, near Bangor. EDWARD GREENLY.

The Cleavage of Slates.

I FIND that I owe Mr. Fisher some apology for a carelessly worded allusion in my notice of Dr. Becker's memoir (p. 20, May 4). In pointing out that the theory which I criticised had been anticipated by Mr. Fisher, I ought, perhaps, to have mentioned that the latter had somewhat qualified his original hypothesis, though the postscript notifying this qualification was, I believe, only privately printed.

Mr. Fisher's further contribution to the question (pp. 55, 56, May 18) is of interest. If it be granted that the cleavage of the Westmorland slates coincides with the plane of greatest distortion, it becomes less necessary to urge the case of the colour-spots in the Llanberis slates; but the suggestion that these have been formed subsequently to the cleavage seems to raise some difficulty. I have seen examples in which the ellipsoidal green spots are shifted by small faults, which are quite obsolete as planes of weakness. This seems to imply that the faults, and *a fortiori* the spots, are older than the cleavage-structure. ALFRED HARKER.

St. John's College, Cambridge, June 7.

The Inheritance of Acquired Characters.

Is the following an instance of such inheritance? Lately I heard a missionary at a May meeting tell of the marvellous facility with which Chinese children memorise whole books of the Bible; the four Gospels, and sometimes the Acts also, being an easy feat for children of ten or twelve years. Having carefully sought information from other authorities, I find these facts confirmed, and that the same applies to Mohammedan children. We are aware that for ages their ancestors have been compelled to memorise long portions of their sacred books, and although occasionally we meet with a child of any nation with a gigantic memory, that differs widely from the case of a people where it has become a general characteristic.

June 7. W. WOODS SMYTH.

THE UTILITY OF AN ANTHROPOMETRIC SURVEY.[1]

THE Government which has shown so scientific a spirit as to create a Council of Defence, a constant spirit of intelligence to safeguard the Empire amid the development of armaments of other nations, might surely devote attention to that recommendation which stands first in the report of the interdepartmental committee on physical deterioration:—"With a view to the collection of definite data bearing upon the physical condition of the population, the committee think that a permanent anthropometric survey should be organised as speedily as possible. . . ."

What are the results to be expected from such a survey as was sketched out at the Cambridge meeting of the British Association last summer? An improvement in the education of the people will surely follow.

At the time of the Elementary Education Act, 1870, the re-distribution of the populace, that progressive change by which the increasing majority become citizens and cease to be country folk, was not realised. The increasing demands of intellectual exercises upon the time of the children and loss of domestic education were not foreseen, or their effect in making the requirement most urgent that the physical side of education should be brought under educational authority or otherwise definitely provided for. Hence a generation passes and there is an outcry for physical education. Let us hope a coming generation may not be crying in turn that the moral side of education suffers from want of due attention.

The effect of registration—the national survey of deaths—has been a clear guide and a very great safeguard to the public health. One may quote some of the words of Dr. Farr which are to be found in his first letter to the first annual report:—"Diseases are more easily prevented than cured, and the first step to their prevention is the discovery of their exciting causes"; again, "indirect influence (of these reports) upon practical medicine must have been very great. The constant endeavour after exactness of diagnosis and precision of nomenclature is itself a wholesome discipline, which reacts inevitably upon treatment." Who at that time could prophesy the value, topographical and historical, we now find in these reports?

The anthropometric survey will have upon the sphere of education an equally large and discriminating, if often indirect, influence; it will react upon medicine as well as upon education; it will detect any deterioration of the young adult that is due to the factory and workshop; it will determine the influence of environment upon physique, and, as Mr. John Gray says, "without an anthropometric survey, we are in this important question of sound national physique 'like a log drifting nowhere'; with a survey, we should be like a ship, steering by chart and compass to its destination."

In the influence of body and mind upon one another, it is to anthropometry we must look for certainty of judgment. Mr. H. G. Beyer pointed out to the

[1] Physical Deterioration; being the Report of Papers and Discussions at the Cambridge Meeting of the British Association, 1904, on the Alleged Physical Deterioration of the People and the Utility of an Anthropometric Survey. (Occasional Papers of the Anthropological Institute, No. 2.)

American Association for the Advancement of Physical Education how important it was to make a study of "fatigue" in its relation to training and education, to find out the conditions under which our work has its maximum beneficial effect, and the limits to the exercise of our muscles favouring the performance of intellectual work. From data worthy of credence, he was of opinion that brain work influenced favourably bodily development, as well as *vice versâ*.

The basis of these and similar observations requires to be broad, and it was interesting to note at the Cambridge meeting how the want of the proposed survey was evident to nearly every speaker. Prof. Cunningham has pointed out how changed conditions of life are palpably attended by changes of physical standard, but we have no clear knowledge of these changes, the best facts concerning our country being still those collected five-and-twenty years ago by the anthropometric committee of the British Association. The racial substitution of a dark element for a fair in the population of London, noted by Dr. Shrubsall as an outcome of his investigations on hospital inmates and healthy individuals, demands a survey to determine its extent and nature.

In the remarks upon deterioration, made at the Cambridge meeting by the president, Mr. Balfour, this requirement stands out quite plainly again in his expression of opinion that fresh air has so large an influence upon the physique of the race.

That a knowledge of the conditions of respiration in towns is at the present day of eminent importance is also patent to everyone who may read, in a recent report of the Registrar General, that in the urban districts of England the death rate from respiratory system diseases is no less than double that of the rural districts.

Now while much attention has been paid to the air of schools and buildings, we have no knowledge whether the lung movement—the chest expansion—of the town dweller is much less than the countryman's, and the answer of a survey to this question is highly desirable. It may be that want of exercise of lung is a deteriorating influence like bad quality of air.

Now that a practical scheme of anthropometry with a responsible recommendation of such a scheme lies before our legislators, concerning a matter absolutely beyond the reach of private effort, surely the nation cannot afford to despise such knowledge, nor is the day past when this country can give a lead in the organisation of information to aid the public health.

Unlike Sweden, Germany, and Italy, we have no conscripts to form a source of similar information. The methods proposed are simple:—height, weight, chest girth; head-length, breadth, and height; breadth of shoulders and hips; vision and degree of pigmentation are to be measured. Economy and efficiency will be observed by the provision of whole time surveyors instructed at a single centre, and 80,000 adults and 800,000 children should be measured annually, re-visiting each district every ten years.

The eugenics of Mr. Galton are not at present practical politics, though, as an analogous subject, it is interesting to note that the stud books of hunters, shires, and hackneys have not only improved the breed, but raised the standard of health and improved the average of health in horses exhibited.

As to expense, the sum required is less than that spent on stud books, and similar to that of the Geological Survey. Provision is made, though not too liberally, for the survey of the land on which we live; surely it is not too much to ask that a scheme for the survey of the people should be established upon a national basis.

PHOTOGRAPHY AND NATURAL HISTORY.[1]

DRY plate photography cannot be altogether regarded as an unmixed blessing. The facilities which it affords to the amateur have brought down upon us a veritable avalanche of books on natural history subjects, some of which had better never have been written.

Mr. Snell's unpretentious little volume is, however, not of this number. On the contrary, it is of its kind excellent, and will prove a boon to those who are fond of nature-photography but, by force of circumstances, are unable to afford an expensive camera or to spend time and money in search of subjects far afield.

Commencing with a most useful chapter on the methods to be adopted in photographing living animals, the author, in the following chapters, demonstrates the practicability of the rules he has laid down. Small mammals, birds, reptiles, Amphibia, fishes, and insects are each, in turn, made to furnish illustrations. Finally, some very valuable hints are given on the photography of botanical subjects.

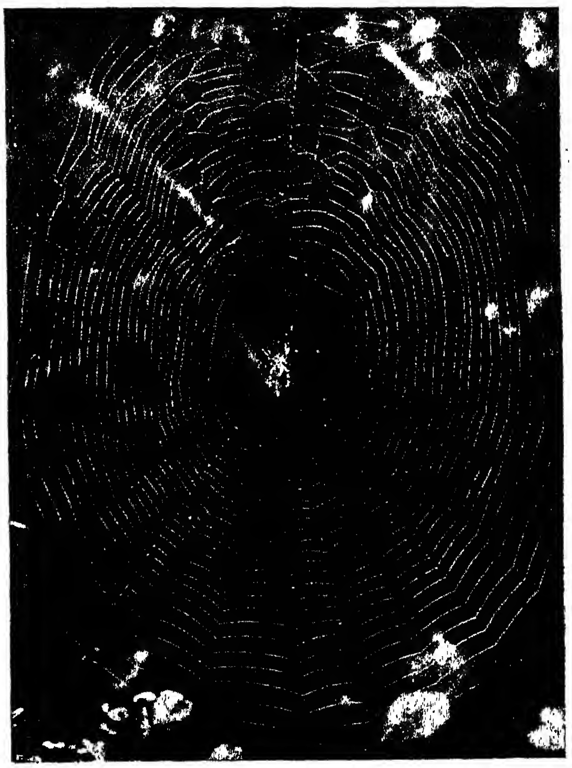

FIG. 1.—Spider's Web or Snare. From Snell's "The Camera in the Fields."

There are tricks, it is said, in every trade! This is notoriously true of photography. Some of the more harmless sort are lucidly described in this volume. The methods, for example, employed in the photography of mice and rats, snakes, and young birds will come as a surprise to many. Many of us, probably, have been amazed at the apparent skill and patience displayed by many "nature-photographers" in securing pictures of field-mice climbing wheat stalks, or rows of nestlings sitting peacefully along a bough. Such pictures, it now appears, may be

1 "The Camera in the Fields." By F. C. Snell. Pp. 256. (London: T. Fisher Unwin, 1905.) Price 5s.

secured in the privacy of a small back yard! It is only necessary first to catch your mouse. This done, he is penned in a glass cage and confronted by the camera. So soon as an attractive posture has been assumed, the exposure is made. A suitable background is all that is needed to deceive even the very elect!

Thus is the mystery explained of some of the wonderful pictures of "wild life with the camera" that have excited the envy and admiration of many who have sought, and sought in vain, in our fields and hedgerows to obtain similar pictures!

The illustrations in this book are unusually good and plentifully distributed. The specimen given herewith was selected with no little difficulty, inasmuch as the high standard of excellence, both in taste and execution, which these pictures present rendered choice difficult. W. P. P.

THE NATURAL HISTORY OF THE BAHAMAS.[1]

TWO years ago there was published in this country an account of a cruise to the Andaman and Nicobar Islands[2] by an American party for the purpose of obtaining natural history and ethnological specimens for the National Museum at Washington, and every Englishman worthy the name who read that work can scarcely have failed to experience a feeling of shame that it was not long ago anticipated and rendered superfluous by the enterprise of his own countrymen. If such a feeling exist in the case of a work dealing in a more or less cursory manner with the results of a private expedition to remote islands of little or no commercial importance, how must it be intensified when we find an American scientific society undertaking a systematic biological, geological, historical, and sociological survey of a group of islands which are supposed to rank among the more important possessions of the British Crown?

That the work should have been undertaken by American enterprise is, *ipso facto*, a confession that it required doing; in other words, that it ought to have been done by Englishmen, and the fact of its being left to our Transatlantic cousins is virtually an admission that our rulers—in spite of what we are being continually told as to the all-importance of science if we are to continue to hold our position as a nation—are blind to the needs and signs of the times in matters scientific! That we should have hitherto possessed no detailed and comprehensive account of a group of islands dotted over an area about as large as the British Islands, which has formed part of our Empire for generations, is, indeed, little short of a national disgrace, and the fact that Americans have cut in and done our own work for us in our own possessions speaks volumes as to the amount of attention that has been paid to the cry of "Wake-up, England!"

The contrast between our own apathy and American enterprise in scientific matters of this nature is intensified when we compare what is being done for the natural history of the Philippines by their new owners with what has been left undone in the case of the West Indies (and many other islands we could mention) by their ancient lords. We were about to urge our rulers, for very shame, to set about doing for the other West Indian islands what Americans have already accomplished for the Bahamas, but we fear we should only be speaking to deaf ears, and therefore refrain. Let us add that in all this we have not one spark of jealousy, but rather unbounded and respectful admiration, in regard to the work our American cousins have so successfully and so thoroughly carried out.

The trustees of the Geographical Society of Baltimore have, it appears, set themselves to accomplish two main objects by means of the body they govern, namely, in the first place, to furnish their public with an annual course of lectures connected with geography, and, in the second place, to foster geographical research in general, and from time to time to publish monographs dealing with some particular piece of geographical investigation carried out under the auspices of the society. The volume before us is the first of these proposed monographs, and its completeness and wealth of illustrations render it a more than usually striking and handsome example of American thoroughness.

The object of the expedition was to investigate the origin and natural history of the Bahamas, and also to conduct studies on lines intimately associated with the well-being of their inhabitants. The scientific staff included no less than twenty-four members, with Dr. G. B. Shattuck as director, most of whom are specialists in one or more particular departments, the special subjects of investigation being geology, tides, terrestrial magnetism and climatology, soils, botany, mosquitoes, fishes, other vertebrates, medicine, and history. Even this, however, by no means represents the full force employed in making public the results of the expedition, for many of the collections were handed over to specialists who did not accompany the latter, the reptiles and amphibians being, for instance, consigned to Dr. L. Stejneger, the birds to Mr. J. H. Riley, the mammals to Mr. G. S. Miller, and so on.

For months previous to the departure of the expedition, the director was engaged in equipping and organising its various sections, procuring the necessary apparatus, so that everything, even down to the most minute detail, should be in such a state of completeness that work might be commenced the very moment of arrival. The expedition sailed from Baltimore on June 1, 1903, equipped for a two months' cruise. Since a number of its members were in Government offices, from which they could only obtain leave during the months of June and July, the length of the cruise had been necessarily limited to that period, and every effort had consequently been made that work should progress with the greatest possible despatch during the time available. Unfortunately, bad weather was experienced during the outward voyage, so that Nassau, the first stopping place, was not reached until June 17, and as it was necessary to start on the return journey before the end of July, only about five weeks were left for work. The more southerly islands of the Bahama group had in consequence to be left unvisited; but apart from this omission, the greater part of the work which had been planned was brought to completion, and all the members of the staff are to be congratulated on the rapidity with which they executed their respective tasks. Except dredging and fishing, most of the work was done on shore, but all the field-work was, of course, merely preliminary to study in the laboratory. In examining the living products of the sea-bed—a sight of rare beauty—great advantage was derived from the glass-bottomed boat which formed part of the equipment.

Our statesmen should not fail to notice that, according to opinion in America, the construction of the Panama Canal in the near future (which is said to be assured) is destined to bring renewed prosperity to

[1] "The Bahama Islands." Edited by G. B. Shattuck. Pp. xxxii+630; 93 plates. [New York: The Macmillan Co.; London: Macmillan and Co., Ltd. (published for the Geographical Society of Baltimore), 1905.] Price 2l. 2s. net.

[2] "In the Andamans and Nicobars." By C. B. Kloss. (London: John Murray, 1903.)

the West Indies, and the hope is expressed by the editor that the facts recorded in the work before us "may be instrumental, if only in a small degree, in causing the Bahama Islands to share" in this prosperity. Commentary on this statement is superfluous.

The picture presented by the islands is well described in the following passage by the editor:—

"No words can describe the beauty of Nassau as one approaches the harbour from the sea. The ocean of deep sapphire suddenly changes to a lagoon of emerald green surrounded by shores of snow-white coral sand. Beyond, the white limestone houses of the town, intermingled with groves of graceful palms, and half-concealed by gorgeous poincianas, rise in a gentle slope against a sky of purest blue. The green transparent water; the intense blue of the sky; the blotches of blood-red poincianas; the snow-white drifts of coral-sand; the vivid green of the foliage—all these unexpected and yet harmonious contrasts strike the eye together, and stamp on the memory a picture of rugged beauty which nothing can efface. The impression thus received does not suffer when later the tourist wanders about the quaint old town to examine at leisure the details of the picture."

Our limits of space allow of only a brief reference to the details of the work of the expedition. An interesting and important feature connected with the geology of the Bahamas is that they are composed almost entirely of débris derived from corals and other calcareous organisms, and rest on a shallow, submerged platform, separated by deep ocean-troughs from the adjacent land-masses of North America and the West Indies. Few of the Bahama animals appear to be distinct from those of the mainland, although some of the mammals have been described (in earlier publications) as separate local races. Of some of these latter the skulls are now for the first time figured. An attractive feature of the volume is formed by the numerous coloured plates of marine Bahama fishes, which convey an excellent idea of the brilliant hues characteristic of all fishes which haunt coral-banks. Of especial interest is the plate of the "mouse-fish" or Sargasso-fish, the remarkable shape and coloration of which are doubtless developed to harmonise with its surroundings of floating seaweed.

This notice may be fitly brought to a close by the expression of our opinion as to the high value and importance of the work initiated by the Baltimore Geographical Society, and by the tendering of our congratulations to all those by whom it has been so successfully and faultlessly executed. R. L.

NOTES.

THE council of the Society of Arts has awarded the Albert medal of the society for the present year to Lord Rayleigh, "In recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

THE De Morgan medal of the London Mathematical Society has this year been awarded to Dr. H. F. Baker, F.R.S., for his researches in pure mathematics.

THE annual conversazione of the Institution of Electrical Engineers will be held at the Natural History Museum, South Kensington, on Thursday, June 29.

THE annual general meeting of the Society of Chemical Industry will be opened on Monday morning, July 10, at University College, Gower Street, when the president, Dr. Wm. H. Nichols, will deliver an address.

THE fourth International Ornithological Congress was opened by Prof. Oustalet at the Imperial Institute on Tuesday. Dr. Bowdler Sharpe, the new president of the congress, delivered an address.

THE death is announced of M. Edouard Simon, the eminent French engineer. He took an active part in the management of the Société d'Encouragement pour l'Industrie nationale, and contributed twenty-four papers to its proceedings.

AT the National Museum at Washington a series of specimens has been arranged to illustrate the associations and mode of occurrence of gold in nature, and Mr. George P. Merrill, the curator, has published in the *Engineering and Mining Journal* a useful list of associations represented in the collection. In the forty-eight cases enumerated, the gold occurs native, and in particles of sufficient size to be recognised by the unaided eye.

WITH the view of lessening the danger of lead-poisoning now encountered by diamond-cutters, the Dutch Government has offered a prize of 6000 florins for the most satisfactory substitute for the tin-lead alloy now used for holding the diamonds during the process of cutting. Applications, which may be written in English, should be sent before January 1, 1906, to Dr. L. Aronstein, Polytechnic School, Delft, Holland.

IN the Free Library at Hampstead there is displayed at present a selection from the collection of flint implements made by the late Mr. Henry Stopes. The exhibit gives a sample, not only of the whole collection, but of that part which deals with the ancient inhabitants of the Thames Valley, and it has been selected to interest the passer-by and educate his eye what to look for in his walks abroad.

Science announces that Dr. Franz Boas has resigned the curatorship of the anthropological department of the American Museum of Natural History. He will continue his connection with the museum, conducting the researches and publications of the Jesup North Pacific Expedition and of the East Asiatic Committee.

A REUTER message from Fort de France (Martinique) dated June 12 reports that Mont Pelée in the past few days has been displaying some renewal of activity. It is reported that on Saturday night, June 10, "the dome suddenly became illuminated. The dome collapsed on Sunday morning, and a mass of mud overflowed into the valley below, while a cloud of smoke rose to a height of 1000 yards."

THE departmental committee appointed by the Board of Agriculture and Fisheries to inquire into the nature and causes of grouse disease has made the following appointments:—Dr. C. G. Seligmann as bacteriologist to the commission, Mr. A. E. Shipley, F.R.S., as expert on the subject of internal parasites, Dr. H. Hammond Smith as assistant bacteriologist and additional field observer, and Mr. G. C. Muirhead as field observer.

THE Anthropological Institute of Great Britain and Ireland has arranged with Mr. J. J. Harrison to publish a full scientific report upon the physical and psychophysical characteristics of the pygmies whom the latter has brought to this country. For this purpose the council of the institute has appointed a select committee consisting of the following anthropologists and medical men, who, with the assistance of Mr. Harrison, will carry on the necessary investigations:—Sir Harry Johnston (chairman),

Prof. Arthur Thomson, Dr. A. Keith, Dr. W. H. R. Rivers, Dr. R. Murray Leslie, Prof. W. Gowland, Mr. J. Gray, and Mr. T. Athol Joyce.

THE committee of the Privy Council appointed to consider and determine certain points in connection with the establishment of a National Museum and National Library in Wales has decided that the two institutions should be separate, the National Museum to be established at Cardiff and the National Library at Aberystwyth. The support, local and otherwise, offered by Cardiff for the foundation and maintenance of the museum and library included:—(1) four acres at Cathays Park (20,000*l.*); (2) collections in municipal museum and art gallery (38,000*l.*); (3) a capital sum of (7500*l.*); (4) public subscriptions amounting at present to (32,500*l.*); (5) a ½*d.* rate under Museums and Gymnasiums Act, 1891 (1940*l.*); and (6) collections of books in municipal library (81,766 volumes and 9118 prints, drawings, &c.) (30,000*l.*).

DR. HENRY DE ROTHSCHILD (says the Paris correspondent of the *Chemist and Druggist*) has recently offered two prizes for competition which will be awarded next year. The first one is a prize of 200*l.* for the best work on the subject of the best alimentary rations of a child from its birth until the age of two years. The second one is a prize of 120*l.* for the best study on the supply of milk to a big city (hygiene, technology, transport, legislation, sale, &c.). These prizes may be divided should the jury of award consider it advisable. The competition is open to foreigners, and papers should be sent in before June 1, 1906. The secretary is M. C. Nourry, 49 rue des Saints-Pères, Paris.

IT was mentioned last week that the U.S. Weather Bureau is taking up the discussion of meteorological observations from the point of view of their relations to solar physics. The programme of the bureau with regard to the coordination of solar and terrestrial observations is, it may be noted, on the lines of the resolution of the Southport meeting of the International Meteorological Committee, which constituted a commission for the express purpose of that coordination. The commission held its first meeting at Cambridge last year, and will meet again at Innsbruck in September. Prof. Bigelow is one of the members, and there is no doubt that the work in this direction of the Washington Weather Bureau will be carried out in cooperation with the commission.

THE provisional programme drawn up and circulated by Prof. Hildebrandsson for the meeting of the International Meteorological Committee, referred to in the preceding paragraph, is mentioned in *Symons's Meteorological Magazine* (May). Among the subjects put forward for discussion are suggestions for improving observations which may be used for the comparison of phenomena over wide areas, especially with regard to noting the exact time of observing each instrument, reducing observations to standard conditions, and the like. Attention is to be directed to the very important question of the causes and the prognostics of widespread heavy rains, the importance of which as affecting floods is naturally felt much more on the Continent than in our country of mild extremes. Prof. Pernter is to suggest a more precise classification of meteorological stations according to the equipment and the nature of the observations carried on. The question of the possibility of extending the use of wireless telegraphy for obtaining reports from the eastern Atlantic, and many others on which an international understanding is desirable, will be taken up.

A LARGE portion of the March issue of the *Proceedings of the Philadelphia Academy* is occupied by the first portion of a paper by Mr. H. A. Pilsbry on the terrestrial molluscs of the south-western United States.

IN the *American Geologist* for April Mr. L. M. Lambe describes in detail, with an excellent figure, the structure of the cheek-teeth of a Canadian representative of the genus Mesohippus, one of the forerunners of the horse.

THE Perthshire Museum, which from the very beginning of its existence has devoted its energies to the illustration of the biology and physiography of the district, has just published an illustrated hand-book to the collection, which forms a short but excellent guide to the animals, plants, and rocks of the county. This is as it should be, and the museum is to be heartily congratulated on the line it has taken up.

IN the *Johns Hopkins University Circular*, No. 5, Mr. E. A. Andrews discusses the so-called *annulus ventralis* of the crayfishes of the genus Cambarus, and confirms the view that its function is to serve as a sperm-receptacle. It is, however, further shown that this structure, which is common to all the members of the genus in question, and is unknown in other crayfishes, is essential to reproduction, and if eliminated would lead to the extinction of the group. In the same issue Mr. R. E. Coker discusses Dr. H. Gadow's theory of orthogenetic variation among tortoises and turtles, and comes to the conclusion (from the examination of a very large number of specimens) that it is not confirmed by the evidence available.

FISHERMEN and fishmongers in Illinois appear to have been aware for some time of the existence of a shovel-beaked sturgeon belonging to a species unknown to science. Eight specimens of this white sturgeon, as it is called by the local fishermen, have, however, recently come under the observation of Messrs. Forbes and Robinson, by whom the species is described as the representative of a new genus, under the title of *Parascaphirhynchus albus*, in the *Bulletin of the Illinois Laboratory of Natural History* (vol. vii., art. 4). Its uniformly light colour, long small eye, long and narrow snout, bare under-parts, small and numerous plates, and superior number of ribs differentiate it sharply from the common shovel-beak or "switch-tail" (*Scaphirhynchus platyrhynchus*). About one specimen in 500 of the sturgeons taken at Grafton, Illinois, belongs to the new species.

THE occurrence of a layer of mesodermic tissue in the anterior part of the head of embryos of the laughing-gull forms the subject of an elaborate article by Mr. H. Rex in parts ii. and iii. of vol. xxxiii. of Gegenbaur's *Morphologisches Jahrbuch*. The occurrence of mesoderm in this part of the head of sauropsidan embryos is, it appears, a comparatively new discovery, and the laughing-gull was selected as a good subject for further investigations concerning this feature. Three articles, two by Mr. G. Ruge and one by Mr. P. Bascho, in the same issue are devoted to the discussion of the nature of certain alleged vestiges in man of the *panniculus carnosus* of the lower mammals, such as the musculus sternalis, and the so-called *achselbogen*. Much turns on whether the former of these muscles constitutes a superficial branch from the upper layer of the pectoral muscles, or whether it has no genetic connection therewith. The view that the structures in question are really functionless representatives of a skin-muscle is supported. In a fifth article Mr. E. Goppert discusses the last part of Dr. Fleischmann's studies on the cranial skeleton of the Amniota.

We have received the year-book for 1905 of the Livingstone College, which gives interesting details of the past year's work, experiences of past students from the mission fields in all parts of the world, and a few hints on risks to health in the tropics and how to avoid them.

The *Journal of the Royal Sanitary Institute* (vol. xxvi., No. 5, June) contains notes on minimum sanitary requirements for building bye laws by Mr. Searles Wood, on isolation hospitals by Dr. Davies, a lecture on canned foods by Prof. Kenwood, and other interesting papers, reviews, and notes.

The *Sitzungsberichte der kaiserl. Akad. der Wissenschaften* (Wien, Bd. cxiii., Heft viii. and ix., Abt. iii.) contains a paper by V. L. Neumeyer on intraperitoneal cholera infection in the salamander; this animal he shows is fifty to sixty times less susceptible than the guinea-pig, an extremely active phagocytosis taking place on injection of the microbe. Prof. M. Löwit contributes an exhaustive study of intravascular bacteriolysis.

Lieut. Christophers, I.M.S., in a third report (*Scientific Mem. Gov. of India,* No. 15), details experiments on the cultivation of the Leishman-Donovan body of kala-azar, a disease of Assam. Rogers and Leishman have obtained flagellated protozoa in cultivations of the parasite. Christophers corroborates this, and although the flagellated forms are very like Trypanosomata, he does not commit himself as to their exact nature.

A fourth fascicle of Mexican and Central American plants, described by Dr. J. N. Rose, and forming vol. viii., part iv., of the *Contributions* from the United States National Herbarium, contains several revisions of genera in addition to the enumeration of many new species. Synopses are provided for Mexican species of Ribes, Parosela, otherwise known as Dalea, and Heterocentron; the opinion that Œnothera is a polymorphic combination leads to the formation of a new genus Raimannia, concurrent with Hartmannia and Lavauxia, and several species of Ternstrœmia are collated under the name of Taonabo.

The Imperial Department of Agriculture for the West Indies has published the full report by Dr. F. Watts on sugar cane experiments in the Leeward Islands during the year 1903-4, and the results are presented in an abridged form in the pamphlet series Nos. 33 and 36. Reference has previously been made to the experiments with different varieties of canes, in addition to which manurial experiments have again been carried out. As the result of trials for four years the conclusion is arrived at that when, as is the custom, pen manure is worked into the soil, no advantage attends the addition of other artificial manures, and that phosphates may even tend to decrease the yield of plant canes. It has, however, been found advantageous to add nitrogenous manures to land planted with ratoon canes. The importance of nitrogenous manures is also affirmed by Prof. J. B. Harrison in his report referred to in the *Agricultural News,* May 6, which relates to sugar cane experiments in British Guiana.

We have recently received three circulars, Nos. 21, 22, and 23, also a bulletin, No. 55, from the Forestry Bureau of the United States Department of Agriculture. Circular No. 33, entitled "What Forestry means to Representative Men," contains extracts embodying the opinions of fifty experts, including President Roosevelt, regarding the value of scientific forestry. They all agree without exception that proper forest conservation is of vital importance to the welfare of the country. That the Department of Agriculture thoroughly realises this fact is shown by circulars Nos. 21 and 22, wherein is set forth the very liberal conditions under which practical assistance is given to farmers, lumbermen, and others in handling their forest lands, as well as the practical assistance offered to all tree planters. Bulletin No. 55, entitled "Forest Conditions of Northern New Hampshire," gives a detailed account of the condition, composition, and stand of timber in this region, with valuable suggestions as to the possibility of extended afforestation and the seemingly much needed forest organisation and conservation in New Hampshire.

The *Century Magazine* for June contains an interesting article by Mr. Gilbert H. Grosvenor entitled "Our Heralds of Storm and Flood," and gives a graphic description of the work of the U.S. Weather Bureau. The author rapidly reviews the whole of the useful operations of this service, but deals more especially with the predictions of floods, cold waves, and storm warnings. The cost of the Weather Bureau and its numerous branches is set down at one million and a half dollars yearly, while the amount of saving to property is estimated at thirty millions. One of the most remarkable cases of flood prediction cited was that of 1903, which was announced twenty-eight days in advance, after torrential rains extending over some 300,000 square miles. This flood caused terrible damage to property, but the public was prepared for it, and the loss was many millions of dollars less than it otherwise would have been. Much care is given to warnings of cold waves in early spring and autumn; the bureau aims at giving at least twenty-four hours' notice of their occurrence, and occasionally issues many thousand telegrams within a few hours. These blighting frosts sometimes destroy in one night the prospects of the agriculturist for the year. The storm warnings issued to the seafaring community form, perhaps, the greatest success of the efforts of the bureau. It is estimated that on the Great Lakes alone, the loss to shipping caused by storms has been reduced by 50 per cent. The article is beautifully illustrated with photographic reproductions of damage by floods, representations of clouds, and the freaks of tornados; the fact of straws, &c., being driven into trees can, fortunately, scarcely be realised in this country.

Messrs. Armbrecht, Nelson and Co. have issued a special price-list of the rare elements and their salts; a noticeable feature is the quotation for 16 oz. bars of metallic calcium. This metal, which for so long has been sold at a prohibitive price, is now obtained by a simple electrolytic process, and has become a comparatively cheap commercial article.

The influence of a magnetic field on luminous radiation forms the subject of the Nobel lecture which was delivered by Prof. Zeeman before the Swedish Academy of Science in 1903, and has recently been printed (Stockholm: P. A. Norstedt & Fils). It deals with the history of the discovery and the theoretical significance of the "Zeeman effect."

The fourth volume of Ostwald's "Annalen der Naturphilosophie" contains a brief sketch, by B. N. Menschutkin, of the life and work of M. W. Lomonossoff. Reference has already been made in these columns (Nature, vol. lxxii. p. 42) to Prof. Menschutkin's more complete study in the Russian language of the work of this eighteenth century philosopher; the present abstract being written in German deserves notice, as it will serve

to make more widely known the views of a man of science whose speculations were in advance of the age in which he lived.

In the *American Journal of Science* (vol. xix. p. 345) Mr. B. J. Harrington describes an investigation of a peculiar variety of fœtid calcite found near the township of Chatham, in the Grenville region of Canada. The calcite, although nearly pure, when struck or scratched evolves a powerful and unpleasant odour, which is shown to be due to hydrogen sulphide occluded in the mineral in minute cavities, probably in the liquid state. The proportion of hydrogen sulphide is about 0·016 per cent. of the weight of the calcite. A striking property of this variety is that when heated to 160° C. it shows a strong, deep yellow phosphorescence, which persists during several minutes after its removal from the source of heat.

In part i. of vol. ix. of the *Transactions of the Royal Dublin Society*, Prof. J. A. McClelland continues the investigation which has already been mentioned in these notes (vol. lxxi. p. 543) of the relation between the atomic structure of substances and their power of giving rise to a secondary radiation under the influence of the β and γ rays of radium. It is shown that as the atomic weight increases the secondary radiation also increases, and that, as regards the latter, the elements may be arranged in a series of groups which correspond strictly with the periods of Mendeléeff's classification. The curve connecting atomic weight and the power of giving rise to a secondary radiation is of particular interest, as it throws light on the manner in which atoms are built up from electrons. It is important to note that the density of a substance has comparatively little influence on its power of producing secondary radiation.

The catalogue of geological literature added to the Geological Society's library during the year ended on December 31, 1904, has just been issued. The catalogue is published by the Geological Society at the price of 2s.

The index number of the *Psychological Review* for 1904 has just been published by the Macmillan Company of New York. The index is a very complete bibliography of the literature of psychology and cognate subjects for the year 1904, and has been compiled by Prof. Howard C. Warren, of Princeton University. It occupies no less than 240 pages, and contains 3445 entries of separate papers or volumes by psychologists of all nations.

OUR ASTRONOMICAL COLUMN.

A Probable Nova in Ophiuchus.—From an examination of the Henry Draper memorial photographs in 1899, Mr. Fleming came to the conclusion that the star R.S. Ophiuchi was of the Nova type. Its spectrum, as shown on a plate taken on July 15, 1898, contained the hydrogen lines $H\zeta$, $H\epsilon$, $H\delta$, $H\gamma$, and $H\beta$, and the lines at $\lambda\lambda$ 4656 and 4691 as bright lines, thus resembling Novæ Sagittarii and Geminorum. A spectrum obtained on July 14, the preceding day, confirmed the presence of these bright lines, whereas one photographed on August 28, 1894, was simply of the K type without bright lines.

Miss Cannon recently examined the light curve of this star since 1888, and found that it varied considerably and rapidly about the time at which the bright line spectra were obtained. Thus on May 31, 1898, the magnitude was only 10·8, but a month later, on June 30, it had become 7·7, and it subsequently decreased, at the regular rate of about one magnitude per month, until on October 8 it was only 10·8 again. A minor recrudescence took place in 1900, followed by another decrease, and since then the magnitude has remained faint at about 10·0, just as other Novæ, e.g. P Cygni, have, since the waning of their initial outbursts, remained fairly constant. An examination of several good chart plates revealed only a single star in the position occupied by this body. As many previous Novæ, having spectra similar to that of this star at its brightest, have been shown to have existed in the same positions prior to their discovery, Prof. Pickering contends that R.S. Ophiuchi should be classed as a Nova, when its proper designation would become Nova Ophiuchi No. 3, the new stars of 1604 and 1848 having appeared in the same constellation (Harvard College Observatory Circular, No. 99).

Observations of Prominences on the Sun's Limb.—In No. 5, vol. xxxiv., of the *Memorie della Società degli Spettroscopisti Italiani*, Prof. Mascari gives, for 1904, his usual annual summary of the observations of solar prominences made at the Catania Observatory. From the tables given we see that the prominence activity was augmented during 1904, also that the law that as the daily frequency of prominences increases their mean heliographic latitude decreases was confirmed; in 1902 the value was 48°·4, in 1903 it was 42°·1, but in 1904 it decreased to 36°·6. During the first quarter of last year the prominences occurred with a greater frequency in the southern hemisphere, but during the other three quarters the reverse was the case, the mean daily frequencies for the year being:- northern hemisphere 1·57, southern hemisphere 1·33.

A plate issued with the preceding number of the same journal shows, graphically, the positions and magnitudes of the prominences observed on the limb during the period March 14 to May 11, 1902, at the observatories of Catania, Kalocsa, Odessa, Rome, and Zurich. By thus combining the observations made at different places, it was possible to obtain a complete daily record for the whole period, with the exception of four days. Several outstanding disturbances are obvious, especially one extending from N. 42° W. to N. 84° W., and enduring as a limb disturbance from March 14 to 18.

Determination of Meteor Radiants.—Commenting on a mathematical paper, on the determination of meteor radiants, recently read before the Royal Astronomical Society by Mr. Chapman, Mr. Denning issues a warning against the acceptance of any radiant, except in special circumstances, determined from the observations of less than five paths. The errors of observation, unless the observer has had much experience, are sufficient to overburden the catalogue of radiant points with a number of false radiants if three paths be accepted as sufficient data. When the altitude of the radiant is small, the meteors traverse long paths, and a consideration of three of these may give a satisfactory value, otherwise three is wholly insufficient. Mr. Denning advises meteor observers to keep a careful record of all faint showers suspected, and endeavour to corroborate them at the subsequent recurrences of the same epochs. By doing this and combining the results, well supported radiants may be established (*Monthly Notices of the Royal Astronomical Society*, April).

THE DEVELOPMENT OF SPECTRO-CHEMISTRY.[1]

The series of optical researches carried on by the late Dr. J. H. Gladstone, at first in collaboration with the Rev. T. Pelham Dale, established the important fact that Newton's expression for refraction, $(n^2-1)/d$, is not constant, but varies considerably with the temperature. On the other hand, it was found that the more simple ratio $(n-1)/d$ remains practically constant.

Soon after 1860, Hans Landolt came forward with his optical researches. He began by confirming the results of Gladstone and Dale. He proceeded a step further, however, by following the example of Berthelot, and comparing the refractivity, not of equal, but of molecular

[1] Abridged from a discourse delivered at the Royal Institution on Friday, May 26, by Prof. J. W. Brühl.

quantities of the substances. If P represents the molecular weight, the product $[(n-1)/d]$P is the *molecular refraction*.

Landolt examined particularly the fundamental question whether a different grouping of the same number of atoms of the same elements—which is the cause of isomerism—has any influence on the optical properties of bodies.

He established the important fact that only the relative weight of the elements is of influence on the molecular refraction of a compound, while the different grouping of the atoms has no appreciable effect; and this made it possible to determine the atomic refractions of the elements. The atomic refraction of carbon, for instance, was obtained by comparing the molecular refractions of two compounds which differed only by one atom of carbon; and in a similar manner the atomic refractions of the remaining elements were determined.

With the aid of these constants it was now possible to calculate *a priori* the molecular refraction of many organic compounds from the elements composing them, and Landolt showed that the calculated molecular refractions agreed very well with those determined by experiment.

Gladstone, in the course of his researches, was able to confirm Landolt's results in many cases. But he also found a considerable number of substances in which the observed molecular refraction was completely at variance with that obtained by adding the atomic refractions together. The exceptions were so numerous that they really seemed to overthrow the whole law of summation.

Shortly before 1880, when I was studying the literature of chemical optics, a brief note published by Gladstone in the *Journal of the Chemical Society* for May, 1870, excited my attention and curiosity. The author there discusses the exceptions to Landolt's rule of summation. He shows firstly that in all such cases the molecular refraction is never found to be too small, but always too great. Then he shows that whole classes of compounds behave in this abnormal fashion.

All optically abnormal compounds proved to be rich in carbon. Gladstone, therefore, examined the effect which a gradual increase of carbon in the composition of a body exerted on its refractivity. He found that there actually was an increase in the excess of the experimental as compared with the calculated molecular refraction, but the increase was not regular enough to explain the anomalies.

The saturated hydrocarbons, or *paraffins*, of the general composition C_nH_{2n+2}, showed *normal* molecular refraction. Also the *olefines*, containing two atoms less of hydrogen, were found normal by Gladstone. On the other hand, the hydrocarbons, containing six atoms less of hydrogen, viz. the *terpenes*, gave molecular refractions about 3 units larger than would correspond to their composition.

With the aromatic hydrocarbons, such as benzene, toluene, &c., containing eight atoms less of hydrogen, this abnormal excess amounted to 6 units:—

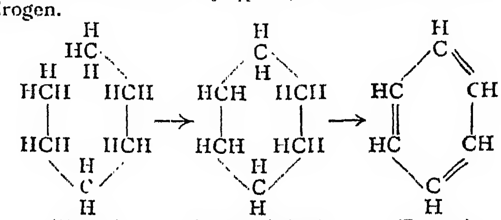
Paraffins	(C_nH_{2n+2})		Normal	
Olefines	,,	$-H_2$	,,	
Terpenes	,,	$-H_6$	,,	+3
Benzene and derivatives ...	,,	$-H_8$	,,	+6

With still further decrease in the quantity of hydrogen contained (*i.e.* with further increase of carbon), there resulted greater and greater refractive increments. The last member of the series, however—pure carbon without any hydrogen, represented by the diamond—proved to be perfectly normal in its optical properties.

It seemed to me really extraordinarily remarkable that all optically abnormal substances, without exception, gave a too *high* molecular refraction. It was no less astonishing to me that the saturated hydrocarbons were optically normal, but became more and more abnormal at successive withdrawals of hydrogen—while pure carbon, uncombined with hydrogen, is again completely normal.

But I was most particularly struck by the quantitative amount of the abnormality in the case of benzene compounds, especially their refractive increment of *six* units. The number 6 fascinated me. I could not help thinking that therein lay the key to the mystery, and I lost no time in making use of it.

According to Kekulé's ingenious hypothesis we can imagine benzene, C_6H_6, to have arisen from the saturated hydrocarbon hexane, C_6H_{14}, by successive removal of hydrogen.



(Hexane) C_6H_{14} (Hexamethylene) C_6H_{12} (Benzene) C_6H_6

Thus altogether four pairs of hydrogen atoms have been removed. The elimination of the first pair was made the occasion to form another *simple* carbon bond, like those already present in hexane, and with it the ring was closed. The splitting-off of the other three pairs of hydrogen atoms, on the other hand, resulted in the formation of three *double* bonds of carbon atoms—a kind of bond which does not occur in the optically normal hexane.

Now Gladstone had found that benzene exhibits a refractive increment of 6 units. Reading this, I was struck in a moment by the thought: might not this abnormal refractive increment of benzene be due to its double carbon bonds, which are absent in the optically normal hexane? If this were so, I went on to reason, since *three* double bonds in benzene correspond to a refractive increment of 6 units, therefore *one* double bond must entail the increment of 2.

These ideas received no support whatever from the then known facts. For Gladstone had stated expressly that the olefines, *i.e.* open-chain hydrocarbons, containing *one* double carbon bond, were optically *normal*. However, I did not allow myself to be discouraged; and my expectations were confirmed by the very first experiment. The olefine examined not only proved to be optically abnormal, but gave the predicted refractive increment of 2 units, corresponding to the presence of *one* double carbon bond. Gladstone, therefore, as I had supposed, was mistaken in this case. Further experiments proved that not one of the olefines was optically normal. Without exception they gave the refractive increment of 2 units, one-third of that of benzene.

I next proceeded to examine the di-olefines—substances which contain *two* double carbon bonds. Here also, in conformity with expectation, a constant refractive increment was found, double as large as that of the olefines and two-thirds of that of benzene:—

Paraffins	(C_nH_{2n+2})		Normal	
Olefines	,,	$-H_2$	,,	+2
Diolefines	,,	$-H_4$	,,	+4
Benzene compounds... ...	,,	$-H_8$	,,	+6

The dimensions of our subject this evening prevent the detailed demonstration of these important facts by experiment. I will only show you that the spectrum of a saturated hydrocarbon (a paraffin) is distinguishable at a glance from that of a substance containing double bonds.

On this screen we project the electric spectrum of metallic calcium. First we cause the rays of light to pass through a prism filled with paraffin oil. Then we exchange this prism for another, filled with a substance containing atoms linked by double bonds. (Experiment.)

In the second case you observe, first, a much greater deviation of the whole spectrum, *i.e.* greater *refraction*, and secondly, far wider intervals between the coloured lines of the spectrum, *i.e.* greater *dispersion*, which is usually correlative to the refraction.

Thus quantitative experimental confirmation was obtained for the view that abnormal refractive increments which increase with the diminution of hydrogen contained in the substances are caused by the presence of double carbon bonds.

At the same time, however, the experiments yielded a second result of fundamental importance. The olefines contain 2, and the diolefines 4, atoms of hydrogen less than the paraffins. Similarly the refractive increment of the olefines is 2, and of the diolefines 4.

Benzene, C_6H_6, contains 8 atoms of hydrogen less than the corresponding paraffin, hexane, C_6H_{14}. The increment of benzene, however, amounts not to 8, but to 6! Thus

in the formation of benzene from hexane, 2 atoms of hydrogen have been eliminated without influence on the refractive increment of the product.

But in the formation of benzene from hexane, 2 atoms of hydrogen have been employed to close the ring (see Fig. on p. 159). The withdrawal of these two atoms, and the closing of the ring, have therefore taken place without causing any optical anomaly.

In the formation of the olefines and diolefines from the paraffins, however, there is no closing of the ring. These substances are of open-chain structure, and *every* removal of 2 hydrogen atoms corresponds here to the creation of a double carbon bond:—

$$H_3C\cdot CH_2\cdot CH_2\cdot CH_2\cdot CH_2\cdot CH_3 \qquad CH_2=CH\cdot CH_2\cdot CH_2\cdot CH_2\cdot CH_3$$

Hexane (C_6H_{14}) Hexylene (C_6H_{12})

$$CH_2=CH\cdot CH_2\cdot CH_2\cdot CH=CH_2$$

Diallyl (C_6H_{10})

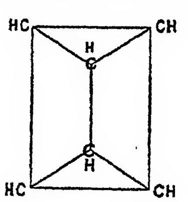
Hence, also, the refractive increment of the olefines and diolefines is directly proportional to the number of hydrogen atoms removed from the paraffin.

From all this it follows that the removal of hydrogen atoms causes optical anomalies only where double carbon bonds are created by the process. *The splitting-off of hydrogen which results in a closing of the ring is, on the other hand, without abnormal optical influence, and produces no refractive increment.*

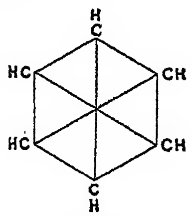
This latter principle, which has since been confirmed many times by experiment, has proved of the same importance as the first in the investigation of the chemical structure of bodies.

A few examples will show how these two principles can be utilised for the discovery of chemical structure.

Besides the formula already mentioned for benzene—that suggested by Kekulé—several others have been proposed, *e.g.* those by Ladenburg and Claus:—



Ladenburg



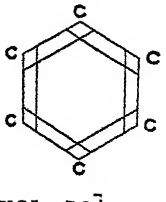
Claus

Neither of these graphic formulæ is reconcilable with the results of spectrochemical investigation, because the neighbouring carbon atoms contained in them are associated only by single, cycloid, or ring-closing affinities, and not by any so-called double bonds. Substances of this kind should be optically normal, while benzene and its derivatives are, as a matter of fact, abnormal. Kekulé's formula for benzene is really the only graphic representation of its structure in a single plane which is confirmed by chemical optics.

Thus it can be at once determined by optical methods whether a given body belongs to the paraffinoid, olefinoid, or cycloid products, whether these products contain double bonds or not, and, if so, how many.

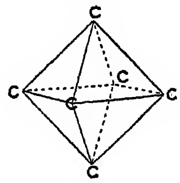
Now, too, we can imagine why the diamond, *i.e.* pure crystallised carbon, is, as already mentioned, optically normal. We obtain an idea of the chemical constitution of the mineral, and of the way in which the atoms of carbon are perhaps combined in the sparkling gem.

For the reasons already stated, the diamond cannot possibly contain any double bonds; a combination, say, in the form



with one atom of carbon at each of the six corners, and with each atom connected with its neighbour by a double bond, is altogether impossible.

Imagine, however, at each of the six corners of a regular octahedron, a single molecule of marsh-gas, CH_4, *i.e.* altogether C_6H_{24}, and then imagine all the 24 hydrogen atoms successively removed, so that each carbon atom is connected with each of its neighbours only by a single bond, and thus all six atoms of carbon are united together in a single whole. Then you obtain, as the most simple representation of the molecule of the diamond, a regular octahedron, with one atom of carbon at each of its six corners, while the edges represent the mutual bonds:—



Several simple molecules of this kind may be combined into one crystallised particle of the spectrochemically normal diamond.

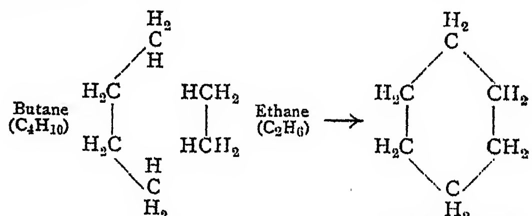
Thanks to the explanation of the optical behaviour of benzene, with the resultant discoveries, it all at once became possible to understand the causes of the spectrochemical abnormality of whole classes of bodies, such as the olefines, diolefines, terpenes, aromatic compounds, &c., and light was cast on the chemical constitution of whole classes of bodies.

At the same time, however, it at once became apparent why both Landolt and Gladstone had succeeded in observing complete optical normality in very numerous substances of the most various types—alcohols, acids, ethers, hydrocarbons, &c. And now it was understood why in such bodies the molecular refraction is determined solely by the component elements, while the different grouping of the atoms, *i.e.* the isomerism, remains without any appreciable optical influence.

All the bodies of this kind proved to be either paraffins, *i.e.* saturated hydrocarbons, or simple derivatives of the same. But the paraffins, as we now know, are always optically normal, because they contain no double carbon bonds. For this reason all such simple derivatives of the paraffins must also be normal. Their molecular refraction will thus always correspond to the elements of which they are composed, however the atoms may be grouped, *i.e.* chemical isomerism is here also without influence.

For the same reason, however, all cycloid (ring-shaped) closed formations, if they contain no double carbon bonds, must be optically normal, for those bodies also may be conceived as originating in the simple replacement of hydrogen by paraffin fragments, and may therefore be regarded as combined paraffins.

Thus we can imagine the hexamethylene already mentioned not only as formed from hexane by removal of *two* hydrogen atoms from the ends, but also as arising from ethane and butane, *i.e.* from two paraffins, by the removal of *four* hydrogen atoms and welding together of the remains:—



Hexamethylene (C_6H_{12})

As a combined paraffin, hexamethylene must be normal, as is also confirmed by experiment, and here we see again, as in the case of the diamond, that a progressive removal of hydrogen and increase of carbon need not lead to the slightest optical anomaly.

At the same time there arises here a case of the optical influence of isomerism, for hexylene, which has already been mentioned, with the same formula (C_6H_{12}) as hexamethylene, but in structure an olefine:—

$$CH_2=CH{\cdot}CH_2\,CH_2{\cdot}CH_2{\cdot}CH_3$$

possesses the familiar refractive increment of 2 units. This example again shows how the spectrochemical behaviour of a body discloses its chemical structure by enabling us to distinguish with certainty between an optically normal cycloid (or ring-substance) and an isomeric open-chain olefinoid formation, which is optically abnormal.

Carbon can thus act variously upon light according to the manner in which its atoms are combined. We can therefore transfer the refractive increment of the double bond to the atom itself.

In the diamond, and in all paraffinoid carbon compounds, the atomic refraction of carbon equals 5; it is therefore equal to 10 for two carbon atoms. The double bond increases the refraction by 2, so that for two carbon atoms with a double bond the refraction amounts to 12. The atomic refraction of *one* carbon atom with a double bond is therefore equal to 6, *i.e.* 20 per cent. greater than that of the atom with the single bond:—

	Atomic Refraction
1 Carbon atom C (diamond and paraffins)	5
2 Carbon atoms 2C (diamond and paraffins) ...	10
Double bond	2
2 Carbon atoms with a double bond (C=C ...	12
1 Carbon atom with a double bond (C=⋮ ...	6

Carbon, being a quadrivalent element, can also appear with *triple* bonds:—

$$R.C{\equiv}C.R$$

Experiment has shown that carbon with a triple bond also acquires a special atomic refraction.

Thus it becomes possible to establish the presence of this kind of bond in substances, and to distinguish it from the double and simple bonds—a further criterion of structure.

In consequence of these discoveries it became highly probable that all multivalent elements, such as carbon, possessed an atomic refraction varying with the kind of bond, while the univalent elements, such as hydrogen, display constant optic values because atoms such as theirs can only be linked with a simple bond.

Later researches have confirmed this. The univalent halogens give, like hydrogen, constant atomic refractions, both in the elementary state and in their compounds. The multivalent elements, on the other hand, such as oxygen and nitrogen, display different optical values, according to the kind of bond.

In the course of such researches the behaviour of oxygen as a quadrivalent element, which had been previously conjectured, was established with certainty, and afterwards confirmed synthetically by Collie, Tickle, and others.

The theory which accounted for the optical abnormalities of certain classes of bodies, making them, in fact, abnormalities no longer, has proved extraordinarily fruitful. It formed the starting point of all subsequent discoveries in the subject, and, indeed, we may describe the progress of this branch of science during the last twenty-five years as based essentially on this conception.

For not until we had fathomed the mystery of the benzene refractive increment 6 was it possible to know for certain that the variable valency of the multivalent elements is always of determining influence on the optical behaviour of bodies. Thus for the first time a spectrochemical method was called into being for the study of chemical structure, and the foundations were laid of what we now call "spectrochemistry."

We must now return once more to the formula for refractivity. Newton's expression $[(n^2-1)/d]P$ had proved not constant for the temperature in the case of fluid bodies, and was, therefore, replaced by Gladstone and Dale's more satisfactory ratio $[(n-1)/d]P$. For twenty years and more this did admirable service. As, however, the number of observations kept on increasing, even this formula betrayed imperfections which finally led to its abandonment. It is impossible here to follow the argument in detail, and we must be content with the remark that comparisons of bodies in different states of aggregation failed to yield satisfactory constants. The values of $[(n-1)/d]P$ for a fluid or solid substance always came out considerably greater than for the same substance in the state of gas or vapour.

Then by a happy chance two physicists, L. Lorenz, of Copenhagen, and H. A. Lorentz, of Leyden, came forward simultaneously in 1880 with a new expression for refraction. One of them started from the ordinary theory of light, the other from Maxwell's electromagnetic theory of light based on Faraday's views, and they both reached the same result, viz. that the true measure of refractivity is furnished by the expression

$$\left(\frac{n^2-1}{n^2+2}\right)\frac{P}{d}$$

Experimental tests showed that this theoretical expression was, in fact, for all bodies, practically unaffected not only by temperature and pressure, but also by the state of aggregation.

Chemical tests confirmed the utility of the new optical standard, since the operation of all the laws before mentioned was observed to be even more exact when the new constant was applied.

Moreover, the expression for refraction proved valuable in another respect. It was found to be very suitable for measuring the *dispersive* power of bodies.

If n_v and n_r denote the refractive indices for the limits of the visible spectrum, *i.e.* for violet and for red light, the difference of the refractivities for these end-rays of the spectrum,

$$\left(\frac{n_v^2-1}{n_v^2+2}-\frac{n_r^2-1}{n_r^2+2}\right)\frac{P}{d}$$

is the measure of the power of different bodies to *disperse* light—to broaden out the spectrum. This ratio proved to be constant as regards temperature, pressure, and state of aggregation.

Gladstone had already observed that dispersion, like refraction, was connected with the chemical nature of bodies. Quantitative relations were, however, only obtained when a constant for refractivity had been found. And then from the molecular dispersions of compounds the atomic dispersions of their elements were deduced.

We cannot enter here into the relations which were thus shown to exist between the chemical composition of substances and their power to disperse light. We need only remark that the case as a whole is analogous to that of refraction. Dispersion is, however, a still more sensitive and more constitutional property, and therefore in many cases it is specially adapted as an aid to research on chemical structure.

It only remains to add a few remarks on the applications of spectrochemistry in science and in practical life.

It has already been shown the principles on which spectrochemical methods of examination in general can be applied to the solution of scientific problems, to the discovery of the chemical structure of single substances or whole classes of bodies.

Now there is a large number of substances, some of them artificially built up by synthesis out of their elements, some of them occurring in the vegetable and animal kingdoms, or even in inorganic nature, the structure of which is of remarkable delicacy and instability. Among them are, for instance, the so-called "tautomeric" compounds, hydrogen peroxide, and many other unstable compounds. Substances of this kind are of a very special interest, for in consequence of their tendency to change, they are the principal cause of metamorphoses, the unceasing circulation of matter, the eternal birth and decay that go on in nature.

Research in the atomic structure of such bodies by purely chemical methods is often very difficult, and not seldom impossible, because, owing to their sensitive organisation, chemical interference leads either to changes in the grouping of the atoms, which cannot always be controlled, or even to total decomposition.

In such cases it is of course of the greatest value to be able to examine the constitution of the bodies without affecting them chemically; and spectrochemistry, as we have seen, gives us the means of doing so. By observing the behaviour of light on its passage through the various substances, we gain an insight into their structure without in any way disturbing it.

In the last ten years the spectrochemistry of the nitrogen compounds has also made remarkable progress. Nitrogen is of the greatest importance as an essential constituent of the proteids, the alkaloids, and many other animal and vegetable products. But its high valency and the extraordinary variety of combinations into which it can enter with other elements surround it with special complications. Regardless of these, however, the spectrochemical examination of nitrogen compounds has already yielded useful results, especially in the study of the alkaloids. It is to be expected that this optical method will also be of use in the chemistry of the albuminoids, the study of which is now being prosecuted with so much vigour.

One class of substances of increasing importance both to science and to chemical industry is that constituted by the natural and artificial perfumes. An overwhelming majority of them consist of derivatives of the terpenes. We have already mentioned that Gladstone, in this subject also a pioneer, was the first to study the optical behaviour of the terpenes. Since then the explanation of the structure of these bodies and of a large number of rich natural perfumes derivable therefrom has been rendered easier by the use of spectrochemical methods. Similar assistance has been rendered to the synthetic preparation of valuable scents, such as ionone, the artificial scent of violets. In every scientific laboratory and in every rationally conducted chemical factory where work is being done on perfumes, the spectrometer is now an indispensable testing instrument, and hence also an implement in industrial production.

When scientific research opens up new methods of observing nature, it is generally not long before a use is found for these methods in practical life. The need is soon felt of perfecting, and at the same time simplifying, the scientific apparatus. Efforts in this direction have not been wanting in the case of the spectrometer, and they have been crowned with the most brilliant success.

Prof. Abbe, the distinguished physicist who died not long ago, and after him Dr. Pulfrich, constructed spectrometers on the principle of total reflection. These instruments are distinguished from those formerly in use by their extraordinary simplicity and convenience, and they allow also of much more rapid work.

Such instruments, known as total reflectometers, have been made for the most exact scientific measurements, and also for medical and technical purposes. Special forms are in use for the examination of fats and oils, milk and butter; to determine the amount of salt contained in salt solutions; the amount of alcohol and extractive matter in beer; for the examination of blood and albuminoids in pathological fluids, &c. Several of these ingeniously contrived instruments give not only the refractive index and the dispersion of a substance immediately, without any calculation, but also directly the percentage of dissolved matter, *e.g.* of alcohol and extractives in beer.

THE MIOCENE FORMATION OF MARYLAND.

We have received from the Maryland Geological Survey a memoir on the Miocene formation of the State, in two volumes, text and plates. This is the second of a series of reports dealing with the systematic geology and palæontology of Maryland, that on the Eocene having been previously published, while reports on other formations are in progress. We may heartily congratulate the State geologist, Dr. Wm. Bullock Clark, on the appearance of these volumes, which in type and illustrations leave nothing to be desired, while the subject-matter, the result of labours extending over fifteen years, represents the combined work of field geologists and of experts in various branches of palæontology.

Of special interest is a chapter by Mr. W. H. Dall on the relations of the Miocene of Maryland to that of other regions and to the recent fauna. He points out that the differentiation of faunas in European and North American areas was well established before the beginning of the Tertiary, so that in the early stages of that epoch the faunas in the west show American characteristics clearly as compared with those of Europe. Other differences, suggesting migrations, occur in the relative time of appearance of certain groups; as, for instance, in America, the first influx of Nummulites is in the upper beds of the lower Oligocene, just as these lowly forms of life were about to disappear from the European fauna, where they had long flourished. In the history of the American Miocene there are many differences and many points of agreement with European equivalents, which are duly pointed out. As in Europe, the Miocene was a period of elevation, of plication of the earth's crust, of denudation, and of the deposition over extended areas of sediment, chiefly of clays, sands, and marls, more or less consolidated. Diatomaceous deposits also occur.

In an introduction Dr. Clark discusses the general stratigraphic relations of the Miocene deposits of Maryland, which have long been known for the rich faunas which they contain. The Oligocene is not represented, and the strata lie unconformably on the Eocene. The palæontological relations, the subdivisions and geographical distribution of the strata are dealt with by Mr. G. B. Shattuck, who gives an elaborate table showing the localities and horizons of the species. The bulk of the volume is taken up with the systematic palæontology, the results of an exhaustive study of the fauna, embracing both a critical review of the species described by previous authors, as well as descriptions of a large number of new forms. As remarked by Dr. Clark, the description of species of fossils is of little scientific importance to the geologist, unless the object is something more than the mere multiplication of new forms. In the present case the endeavour has been made to clear up doubtful points in synonymy and to give as complete an account as possible of the geological and geographical ranges of the fossils. All groups from the Mammalia to the Radiolaria, Foraminifera and plants come under notice. The higher vertebrates are dealt with by Dr. E. C. Case, the fishes by the late Dr. C. R. Eastman, many of the invertebrates by Dr. G. C. Martin, the Echinodermata by Dr. Clark, and the remaining groups by other authorities.

The palæontology is illustrated by 135 plates, while in the volume of text there are sections, numerous pictorial views, and a coloured geological map. The work is well indexed, and there is a useful geological bibliography.

MINERAL PRODUCTION OF INDIA.

An interesting new departure has been made by the Geological Survey of India in devoting the last issue of the *Records* (vol. xxxii., part i.) to a review of the mineral production of India during the years 1898 to 1903, by Mr. T. H. Holland, F.R.S., director of the Survey. This review, which covers 118 pages, with 6 plates, compares very favourably with the statistics of many countries where the facilities of obtaining information regarding the mineral production are far greater than in India. The period covered is six years, and it is intended in future to issue quinquennial reviews. The minerals are divided into two groups:—(1) those for which fairly trustworthy returns are available, and (2) those for which definitely recurring particulars cannot be procured. It is curious to note that in the review of mineral production in India issued by Sir George Watt in 1894, four minerals, salt, coal, iron ore, and petroleum, were the only representatives of the first group, whereas it is now possible to obtain trustworthy returns of the production of thirteen minerals, coal, gold, graphite, iron ore, jadeite, magnesite, manganese ore, mica, petroleum, rubies, salt, saltpetre, and tin.

The production of salt, which was 358,000 tons in 1898 and 336,000 tons in 1903, showed considerable fluctuations during the period under review; but in the case of all other minerals there was substantial progress. The Indian coal output rose from 4,000,000 tons in 1897 to 7,500,000 tons in 1903. The production of gold steadily increased from 390,505 ounces to 603,218 ounces. The production of saltpetre also increased, the average

annual exports having amounted to 382,000 cwt. The petroleum industry increased at a greater rate even than coal mining, the production having risen from 19,000,000 gallons in 1897 to 88,000,000 gallons in 1903. Rubies form, next to petroleum, the chief source of revenue from minerals in Burma, the value of the output having risen from 57,950*l*. to 98,575*l*. In the case of mica, India is the leading producer, and supplies half the world's consumption. The value of the mica produced in 1898 was 53,890*l*., and in 1903 86,277*l*. The waste heaps are now turned over to supply the cheaper varieties required for the manufacture of micanite for electric insulation. The rapid development of the manganese ore industry has been very remarkable. Twelve years ago mining had hardly begun, and now more high-grade ore is produced than in any other country except Russia. The value of the output in 1898 was 27,426*l*., whilst in 1903 it was 132,741*l*. Jadestone, which is being exported in increasing quantities to the Straits and China, with an average annual value of 44,770*l*. for the mineral exported, must be classed among the important minerals, its value being seven times that of the tin and half that of the rubies. Iron ore is mined to supply the Barakar works and the old charcoal furnaces still persisting in the more remote districts. In view of the fact that the imports of iron and steel are increasing year by year, there appear to be good grounds for utilising the abundant ore supplies by starting iron works on a large scale. During the period under review the graphite deposits of Travancore and the magnesite deposits of Salem received attention, and now form serious items in the comparatively limited markets of these minerals. Tin is more widely distributed in India than is generally recognised, and in South Burma river gravels are washed for tin with considerable commercial success.

The minerals for which statistics of production are incomplete are of a very varied nature, the list including alum and aluminium ore, amber, antimony, arsenic, asbestos, borax, building stones, chromite, clays, copper ore, corundum and other abrasives, gem stones, glass-making sands, lead, silver and zinc ores, millstones, mineral paints,. mineral waters, phosphates, rare earths, slate, sodium compounds, steatite, and sulphur. It is evident that there is great scope for development in the mining of metalliferous minerals and of minerals that are needed for the more complicated chemical and metallurgical industries. This is not surprising in view of the fact that by-products are indispensable sources of profit in modern chemical and metallurgical practice; and India must continue to pay taxes on imports until industries arise demanding a sufficient number of chemical products to complete an economic cycle. Until that time, ores that will not pay to work for their metal contents alone must necessarily be neglected.

DISEASES OF FOREST TREES.

THE Board of Agriculture and Fisheries has recently issued a set of nine diagrams illustrating the diseases of forest trees. The set is composed of forty-five coloured figures. Very scant attention has been paid to this important branch of forestry in the past, and it is only within comparatively recent times that such works as those of Hartig and Sommerville, Tubeuf and Smith, Marshall Ward, Massee and others have directed attention to the importance of the study of tree diseases from a practical point of view. By such means the public has come to realise that plants, like animals, are subject to various ailments which, if not attended to, may become epidemic and cause serious loss, not only in forestry, but also in the sister industries of agriculture and horticulture. As an instance of the serious loss which may be caused by fungus disease in trees, we need only mention the larch canker fungus, which has in many cases reduced one of the most stately trees of Europe to an unsightly cripple, and is thereby responsible for the loss of many hundreds of thousands of pounds in this country alone. Its ubiquity in this country is no doubt in a large measure due to the lack of proper care in the selection of localities and proper treatment of this timber tree. This is only one of the many examples of the havoc which may be wrought by epidemics among forest trees, and in addition to this the fruit-grower, the farmer, and the gardener could also furnish parallel examples to swell the list. As we have already stated, the importance of these matters is becoming greater as scientific investigation proceeds. It is of vital importance in practice that a plant disease of any kind should be recognised in its earliest stages, as it is then in most cases capable of being stamped out. It is too late to adopt preventive measures when the presence of the disease is made known by the destruction of the crop.

The importance of the whole subject to the public in general is shown by the fact that the Board of Agriculture has issued the above valuable series of diagrams, each illustration being accompanied by a printed description on a separate sheet.

The set contains the best series we have of the diseases of forest trees, and should find a place not only in all our universities and colleges, but in every school throughout the country. It is absolutely indispensable to all foresters and to those interested in the growth and production of timber.

The price, which is one shilling per diagram, should bring the set within the reach of all.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The council of the Senate has had under its consideration an offer received from the Surveyors' Institution to provide scholarships in the university, with the object of affording facilities for the higher education of surveyors in branches of scientific knowledge cognate to their profession. The council, after consultation with the Board of Agricultural Studies, is of opinion that the offer should be gratefully accepted. The scholarships will be called "The Surveyors' Institution Scholarships"; they will be three in number, one to be awarded annually. Each scholarship will be tenable for three years, and will be of the value of 80*l*. per annum.

The general board of studies has approved the name of Mr. A. N. Whitehead for the degree of Doctor in Science.

In the mathematical tripos, part i., the senior wranglers (bracketed equal) are Mr. J. E. Littlewood and Mr. J. Mercer, both of Trinity.

OXFORD.—The following have been appointed examiners in the science schools:—P. J. Kirkby (physics), D. H. Nagel (chemistry), Gustav Mann (physiology), J. G. Kerr (zoology), Robert Howden (anatomy), James Ritchie (pathology), D'Arcy Power (surgery), W. W. Fisher (preventive medicine and public health).

Decrees have been passed to authorise the expenditure of 475*l*. on extending the system of electric lighting in the university museum, to raise the total emoluments of the Wykeham professor of physics to 800*l*. a year, and to raise the salary of his demonstrator in advanced work by 100*l*. a year, so that he may take charge of the laboratory both in vacation and term time on occasions of the absence of the professor.

The honorary degree of D.Sc. has been conferred on Prof. Ray Lankester, who delivered the Romanes lecture on June 14, and the degree of D.M. on Prof. William Osler.

Only one man of science—Prof. G. H. Darwin—is included in the list of honorary degrees for the Encænia this year.

PROF. A. S. MACKENZIE, professor of physics in Bryn Mawr College, has been appointed to the chair of physics in Dalhousie College.

THE Senate of the University of Birmingham has decided to invite Sir Archibald Geikie, F.R.S., to deliver the Huxley lecture in 1906.

WE learn from *Science* that it is announced that Harvard University has received an anonymous gift of 20,000*l*. for a museum of social ethics, and 10,000*l*. from Mr. Jacob H. Schiff, of New York, for explorations in Palestine.

AN exhibition of practical work executed by students of technical classes and by candidates at the recent annual examinations of the City and Guilds of London Institute will be opened at the Imperial Institute on Wednesday, June 28, by the Right Hon. Earl Spencer.

THE announcement is made in *Engineering* that Mr. Yarrow has placed at the disposal of the council of the Institution of Civil Engineers the sum of 10,000*l.* to be applied to the education of necessitous members of the engineering profession. It is pointed out that the engineering industry of the country will benefit from this help to technical education. The old system of premium apprenticeship is passing away, and it is coming to be recognised that the prosperity of any manufacturing nation rests on engineering, and that a foundation for the commercial success of a country cannot be maintained without the aid of a body of scientific engineers. The era of happy-thought invention is fast passing, and the opportunity for original work must chiefly depend on the application of science to perfecting known principles. Gratitude should, therefore, be felt for the public spirit which has placed in the hands of the Institution of Civil Engineers the means of giving a better training to a class that has had few opportunities in the past.

THE foundation-stone of the new buildings of University College, Reading, was laid on June 6 by Lord Goschen, Chancellor of the University of Oxford. The freehold of the new buildings is a gift to the college by Mr. Alfred Palmer. The erection of the college hall and the buildings for the practical study of various branches of pure and applied science will be undertaken immediately, but substantial additions must be made to the building fund before the scheme as a whole can be carried out. At the luncheon following the ceremony, Mr. W. M. Childs, the principal of the college, said the day would be memorable in the annals of the college because of a splendid benefaction. Throughout its history the college had been exposed to peril by the absence of endowment. He then announced that Mr. George William Palmer had informed the president of the college of his intention to offer a sum of 50,000*l.* as a permanent endowment fund, to be called "The George Palmer Endowment Fund." In a letter to the president announcing his intention, Mr. Palmer said:—"My intention is to provide that the capital fund of the endowment shall not be applied to the erection of buildings, but shall be permanently invested, and that the income shall be applied to the educational work of the college. I also desire to make it a condition of my gift that the college shall maintain its *status* as a university college in the town of Reading, and that it shall always give higher teaching in literature and in science, and, further, that it shall carry on evening classes, open at moderate fees to those engaged in earning their living during the day-time." Lord Goschen, in the course of a few remarks, referred to the direct missionary work which had been conducted by the old universities through the university extension lecturers. They were, he said, the missionaries of culture throughout a great part of our islands, and they had carried the flag of culture into many a town. A great variety of subjects is now taught in the college, but all that is taught, said Lord Goschen, is taught in a thorough, academic, and scientific manner. It is for the professors to see that the cause of culture, the cause of scientific study, shall not be neglected in these days. "Amid the hustling of those who champion various causes," continued Lord Goschen, "may I at least put in a word for higher culture? May I echo what Mr. George William Palmer has written, that literature and science may hold their own in this country apart from useful knowledge?" The president of the college announced that 80,000*l.* is required for the building fund, and of that sum 35,700*l.* has been subscribed.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, May 11.—"On the Resemblances existing between the 'Plimmer's Bodies' of Malignant Growths, and Certain Normal Constituents of Reproductive Cells of Animals." By Prof. J. Bretland **Farmer**, F.R.S., J. E. S. **Moore**, and C. E. **Walker**.

The authors, continuing their investigations on malignant growths, have examined the so-called "Plimmer's Bodies" of cancer cells in connection with the cytological changes that occur in cancer and in reproductive cells respectively. The "Plimmer's Bodies" are found in many cancerous growths, and are most commonly encountered in the younger or growing regions of the tumour. They appear in the form of vesicles, and they consist essentially of a fairly well defined wall containing a clear space in which is suspended a small darkly staining granule (Figs. 1 and 2). They are most commonly to be met with in

FIG. 1.

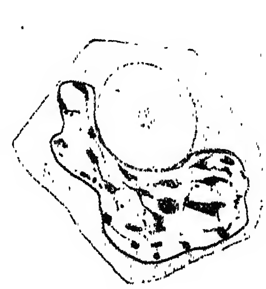


FIG. 2.

FIGS. 1 and 2.—Examples of "Plimmer's Bodies" from carcinoma. 1. Three small "Bodies" in an archoplasm. 2. Later stage in the development of the "Bodies."

tumours of a glandular or glandular-epithelial origin. They lie in the cytoplasm of the cancer cell, and usually in close proximity to the nucleus. In size, they vary from excessive minuteness to that of the nucleus itself.

The special interest attaching to them depends on the fact that they have commonly been regarded as peculiar to cancerous cells, although Honda believes he has occasionally also encountered them in inflammatory tissues. They have been variously interpreted. Some investigators have regarded them as parasitic organisms, more or less intimately connected with the etiology of the disease, whilst others have seen in them a differentiation of the cytoplasm of the cancerous cell itself. It has been suggested also that they might be derived from the centrosomes within the archoplasm, but the observations of Benda that centrosomes coexisted independently of them in the cell have rightly been held to disprove this hypothesis.

FIG. 3.—Archoplasm with centrosomes lying outside it in prophase of the first maiotic division in testis of mouse.

The authors' investigations indicate, however, that there are good grounds for re-considering the whole position, and a comparison of the processes that normally obtain during the final stages of development of the reproductive elements in man and the other mammalia appears strongly to suggest that a parallel between the "Plimmer Bodies" of cancer and certain vesicular structures occurring regularly in the gametogenic, but not in the ordinary somatic, cells, may be found to hold good.

It was shown in 1895 that during the prophase of the heterotype (first maiotic) mitosis of the spermatogenetic cells, the archoplasm undergoes a highly characteristic and peculiar metamorphosis. In normal somatic, or pre-maiotic, cells, the archoplasm is seen to lie beside the nucleus as a dusky mass of protoplasm in which are con-

tained the centrosomes. That is, the attraction sphere consists of the archoplasm *plus* the centrosomes.

But during the prophase of the heterotype mitosis these constituents become separated. The centrosomes are found to lie *outside of*, and detached from, the archoplasm (Fig. 3). At the same time the archoplasm itself undergoes a change. It becomes vesiculated, and finally, at the close of this cell generation, it is lost in the general cytoplasm of the daughter cells.

In the prophase of the second maiotic division (homotype) the same phenomena recur. When the homotype mitosis is over, the constituents of the sphere, or at least some of them, enter into direct relation with parts of the

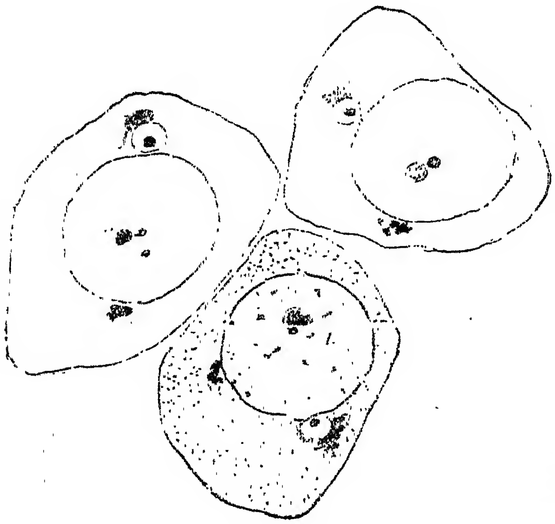

FIG. 4.

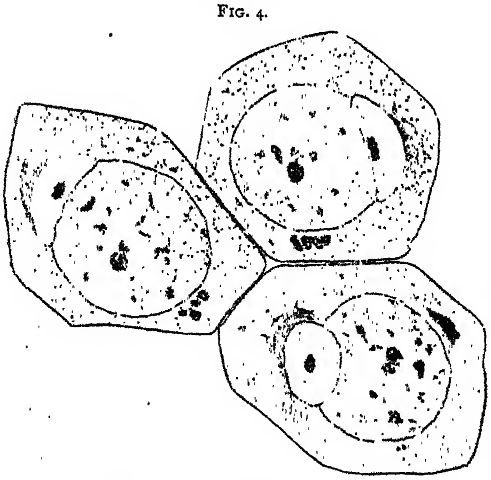

FIG. 5.

FIGS. 4 and 5.—Later stages in the development of the spermatid of mouse.

spermatozoon which arises by further differentiation of the cell. As regards the archoplasm, it is again seen to contain a number of minute vesicles which continue as before to grow in size, whilst each contains a single refractive and stainable granule (Fig. 3). Subsequently, several of these vesicles fuse together, so that at a later stage in the metamorphosis of the cell into a spermatozoon there only remains a single large clear body, bounded by a distinct membrane, containing in the centre one or more darkly staining granules (Figs. 4, 5, 6).

This body, originally described in 1895 as the archoplasmic vesicle, is a very conspicuous and apparently constant feature peculiar to the spermatogenetic cells of, at any rate, the Vertebrata, and it has since been encountered beyond the limits of that group.

When fully developed it often assumes a size approximating to that of the nucleus. Indeed, the latter is often deformed and made to assume a crescentic or cup-like shape owing to the enlargement of the adjacent archoplasmic vesicle. The vesicle and its contents ultimately form the so-called "cephalic cap" of the spermatozoon.

The remarkable similarity between the structure just described and those known as "Plimmer's Bodies" will have become obvious. It is not, perhaps, accidental that just as in the case of nuclear divisions, so also in the cellular inclusions, a parallelism between the cells of reproductive tissues and of cancer cells should be found to exist. But the cells of cancer are not therefore regarded as *identical* with those of the sexual cells, as was carefully pointed out in the first communication of the authors in 1903.

But the resemblances between what have been termed gametoid and the true gametogenic cells now seem to be even more significant than they appeared to be at that time. Both classes of cells are autonomous to a very high degree, and both possess the faculty of continuous or intermittent multiplication independently of the tissue requirements of the organism. And finally, both exhibit cellular and nuclear metamorphoses which not only, *mutatis mutandis*, resemble one another, but differ materially from those pertaining to the normal somatic cells.

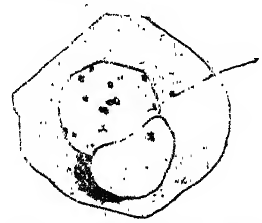

FIG. 6.—Slightly later stage in the spermatid of man, with centrosomes and tail.

It is possible that the malignant elements are the outcome of a phylogenetic reversion, but the matter is obscured by the disturbing influences that have been operative during the actual ontogeny of the cells and tissues from which these elements have sprung. If this be so, the connection apparent between gametoid and the true reproductive cells will acquire a still deeper significance; the full discussion of this question is reserved for another occasion.

May 18.—"The Atomic Weight of Chlorine: an Attempt to Determine the Equivalent of Chlorine by Direct Burning with Hydrogen." By Prof. H. B. **Dixon**, F.R.S., and E. C. **Edgar**.

In the whole of nine experiments described by the authors 9·1786 grams of hydrogen combined with 323·0403 grams of chlorine; hence the equivalent weight of chlorine, calculated in mass, is 35·195.

The number obtained for the atomic weight of chlorine is appreciably higher than that calculated by F. W. Clarke from the previous determinations, and is slightly higher than Stas's value:—

Clarke's calculation	Stas	Dixon and Edgar	
35·179 ...	35·189 ...	35·195 ...	H = 1
35·447 ...	35·457 ...	35·463 ...	O = 16

G. P. Baxter quotes the value 35·467 as being obtained by Richards and Wells for the atomic weight of chlorine —a number slightly higher than the authors'.

Chemical Society, June 1.—Prof. R. Meldola, F.R.S., president, in the chair.—The constituents of the seeds of *Hydnocarpus Wightiana* and of *Hydnocarpus anthelmintica*. Isolation of a homologue of chaulmoogric acid: F. B. **Power** and M. **Barrowcliff**. The authors found that the oils of these two seeds very closely resemble chaulmoogra oil, consisting chiefly of the glyceryl esters of chaulmoogric acid and a lower homologue of the same series, which has the formula $C_{16}H_{28}O_2$, and is designated *hydnocarpic acid*. The oil of *Hydnocarpus Wightiana* appears to contain also a very small proportion of an acid or acids belonging to the linolic or linolenic series.—The constituents of the seeds of *Gynocardia odorata*: F. B. **Power** and M. **Barrowcliff**. The oil expressed from the seeds was found to consist of the glyceryl esters of linolic acid or isomerides of the same series, palmitic acid, linolenic and *iso*linolenic acids, and oleic acid.—The relation of ammonium to the alkali metals. A study of

ammonium magnesium and ammonium zinc sulphates and selenates: A. E. H. **Tutton.** With regard to molecular volume, the topic axes, and molecular refraction, the ammonium salt of any double salt group of the series behaves almost exactly like the rubidium salt.—Camphorylazoimide: M. O. **Forster** and H. E. **Fierz.**—Influence of substitution on the formation of diazoamines and aminoazo-compounds, part iii., azo-derivatives of the symmetrically disubstituted primary *meta*diamines: G. T. **Morgan** and W. O. **Wootton.** The following new diamines have been prepared and characterised:—6-*chloro*-4-*nitro*-m-*phenylenediamine*, 6-*bromo*-4-*nitro*-m-*phenylenediamine*, and *di-iodo*-m-*phenylenediamine*.—Diazo-derivatives of monoacylated *para*diamines: G. T. **Morgan** and F. M. G. **Micklethwait.**—The significance of optical properties as connoting structure; camphor-quinone-hydrazones-oximes: a contribution to the theory of the origin of colour and to the chemistry of nitrogen: H. E. **Armstrong** and W. **Robertson.**—Solubility as a measure of the change undergone by isodynamic hydrazones. (1) Camphorquinonephenylhydrazone; (2) acetaldehyde-phenylhydrazone: W. **Robertson.**—The design of gas-regulators for thermostats: T. M. **Lowry.** Two new patterns are described. By means of one of these the temperature of a bath of water may be maintained within $\pm 0^{\circ}.01$ C. during several weeks, the average fluctuation being about $\pm 0^{\circ}.002$ C.—The constitution of barbaloin, part i.: H. A. D. **Jowett** and C. E. **Potter.** The authors have made a number of analyses and molecular weight determinations of carefully purified barbaloin and tribromobarbaloin, and their results agree best with Tilden's formula.—Influence of substitution on the formation of diazoamines and aminoazo-compounds, part iv., 5-bromo-*as*(4)-dimethyl-2-4-diaminotoluene: G. T. **Morgan** and A. **Clayton.**—The action of magnesium methyl iodide on pinenenitrosochloride: W. A. **Tilden** and J. A. **Stokes.** Two principal products are obtained, the oxime $C_{10}H_{15}(CH_3):NOH$ (m.p. 193°), and a base $C_{10}H_{16}N(CH_3)_2$ (m.p. 122°).—The action of hypobromous acid on piperazine: F. D. **Chattaway** and W. H. **Lewis.**—Racemisation phenomena during the hydrolysis of optically active menthyl and bornyl esters by alkali: A. **McKenzie** and H. B. **Thompson.**—Estimation of hydrogen peroxide in the presence of potassium persulphate: J. A. N. **Friend.** The author now shows that if a slight excess of permanganate is rapidly added from a burette to the mixture of peroxide and persulphate, and the excess of permanganate estimated iodometrically with thiosulphate, accurate results may be obtained in the presence of any weight of potassium persulphate not exceeding 0.08 gram.—Some oxidation products of the hydroxybenzoic acids and the constitution of ellagic acid: A. G. **Perkin** and M. **Nierenstein.**—The reduction of *iso*phthalic acid, part ii.: W. L. **Goodwin** and W. H. **Perkin,** jun. The authors describe a convenient method for the preparation and separation of the *cis*- and *trans*-modifications of hexahydro*iso*phthalic acid.—Complex ammonium antimonious halides: R. M. **Caven.**—The replacement of hydroxyl by bromine: W. H. **Perkin,** jun., and J. L. **Simonsen.** The authors find that good results are obtained when the acetate of the alcohol is heated at about 150° with a solution of hydrogen bromide in acetic acid (saturated at 0°).—The ethereal salts and amide of dimethoxypropionic acid derived from *d*-glyceric acid: P. F. **Frankland** and N. L. **Gebhard.**—The influence of phosphates on the fermentation of glucose by yeast juice. Preliminary communication: A. **Harden** and W. J. **Young.** It has previously been shown by the authors that the amount of glucose fermented by a given volume of yeast juice is greatly increased by the addition of boiled and filtered yeast juice. A similar initial rapid evolution of carbon dioxide occurs when a solution of sodium or potassium orthophosphate is added instead of the boiled juice, but in this case no marked prolongation of the fermentation is observed.—A contribution to the study of alkylated glucosides: J. C. **Irvine** and A. **Cameron.**

Linnean Society, June 1.—Prof. W. A. Herdman, F.R.S., president, in the chair.—Models of restorations of some extinct Dinosaurs, Ceratosaurus and Diplodocus, also of Ichthyosaurus, Plesiosaurus, Scelidosaurus, and Stegosaurus: H. E. H. **Smedley.**—Two photographs of a palm, *Corypha elata*: J. F. **Waby.** At the general meeting of June 18, 1903, photographs were shown of two specimens of equal age; one had normally flowered, fruited, and died; the other, instead of flowers, had thrown up a secondary central growth of leaves. The information now sent completes the record; the survivor in its turn had flowered and died, the inflorescences being developed from the secondary crown of foliage. On being cut down it proved to be 68 feet in height, diameter at base 3 feet 6 inches, diameter at base of secondary growth, 1 foot 10 inches. The secondary growth itself was 4 feet in height, and the height of the spadix an additional 20 feet, 5 feet of this being bare stem, the remaining 15 feet crowded with twenty-nine huge branches. The crop of fruit numbered more than 51,000 and weighed half a ton, most of the spadices being abortive.—The botany of Gough Island, part ii., the cryptogams, exclusive of the ferns and unicellular algæ: R. N. Rudmose **Brown.** The president reminded the meeting that when part i. of this paper was read on May 4 it had been suggested that a visit to the Tristan da Cunha group might form part of the programme of the Cape session of the British Association. The matter had, however, received so little outside support that the project had been abandoned.

Geological Society, June 2.—Dr. J. E. Marr, F.R.S., president, in the chair.—On the igneous rocks occurring between St. David's Head and Strumble Head (Pembrokeshire): J. V. **Elsden.** The author finds that the contemporaneous lavas of the Llanrian area agree generally in character with the eruptive rocks of apparently Ordovician age in the Strumble Head and Prescelly districts. These are all of an essentially acid type. The intrusive rocks of the area are of later date, and belong to three distinct types:—(1) the gabbros and diabases of the Strumble Head area; (2) the norites and associated rocks of St. David's Head and the surrounding district; and (3) the lime-bostonites and porphyrites of the Abercastle-Mathry district. Detailed petrographical descriptions of the different types are given, accompanied in many cases by analyses and comparisons with corresponding or related rocks of other areas.—The Rhætic and contiguous deposits of Glamorganshire: L. **Richardson.** The chief sections in the county described in detail are those at Lavernock (near Cardiff), Barry, Tregyff (near Cowbridge), Quarella (Bridgend), and Stormy Down. The Sully beds, a name given to the fossiliferous portion of the "Grey Marls" of Etheridge, are determined to belong to the Rhætic series, on account of the fossils that they contain. They are quite distinct from the "Tea-Green Marls," in which fossils have not been observed.—On the occurrence of Rhætic rocks at Berrow Hill, near Tewkesbury (Gloucestershire): L. **Richardson.** About two miles south-east from Chase-End Hill (Malvern Hills) there is a small outlier of Lower Liassic and Rhætic beds, in a basin-shaped area, supported and surrounded by Keuper Sandstone. A detailed section is given, mainly obtained by excavation, and this is compared with the nearest locality where the whole of the Rhætic may be studied, namely, at Wainlode Cliff.

Cambridge.

Philosophical Society, May 15.—Prof. Marshall Ward, president, in the chair.—Exhibition of lantern slides of fungi: Prof. Marshall **Ward.**—Infection phenomena in various species of Uredineæ: I. P. B. **Evans.**—The abortive development of the pollen in certain cross-bred sweet peas: R. P. **Gregory.** Among the offspring produced by the self-fertilisation of a certain hybrid sweet pea, Mr. Bateson obtained, during 1903, a certain number of individuals the anthers of which were contabescent. The same phenomenon was repeated in 1904, with every indication that the sterility is a character which undergoes segregation in accordance with Mendelian principles. The above paper dealt with the abnormalities observed in the nuclei of the pollen-mother-cells of the sterile plants. The vegetative mitoses are perfectly regular, the first indication of abnormality being observed in the prophase of the heterotype (reduction) division. From this point onwards the distribution of the chromatin becomes more and more irregular, with the result that no normal pollen is pro-

duced. The sterility is confined to the male organs, and the development of the embryo-sac is normal.—Crosses between fully fertile varieties of barley and varieties bearing unisexual and sexless flowers: R. H. **Biffen.**—The seed-bearing habit in the Lyginodendreæ: E. A. N. **Arber.** Although the seed (Lagenostoma) of Lyginodendron, one of the most fern-like of Upper Palæozoic plants, is known, there has, so far, been no evidence as to the manner in which the seeds were borne. A new species, *Lagenostoma Sinclairi*, has, however, been recently discovered, in which the seeds are still attached to a highly branched axis, which is of the nature of a compound frond with reduced lamina. In this respect the Lyginodendreæ agree with the other known members of the class Pteridospermeæ.—Experiments on penetrating radiation: H. L. **Cooke.** The experiments described are in continuation of a previous research by the author on penetrating radiation. By means of a small portable ionisation vessel the radiation in the Cavendish Laboratory is compared with that on the roof of the building; also when the apparatus is buried in earth, and when deeply submerged in water. A discussion of the results follows.

DUBLIN.

Royal Dublin Society, May 16.—Dr. W. E. Wilson, F.R.S., in the chair.—The influence of water-vapour upon nocturnal radiation: J. R. **Sutton.** The author shows a connection between the rate of cooling of a thermometer exposed between 8 and 10 p.m. near the surface of the ground and the relative humidity of the atmosphere, and points out that his observations will not permit of any such connection between the rate of cooling and the absolute humidity. The observations were made at Kimberley, South Africa.—On floating breakwaters: Prof. J. **Joly.** A description of breakwaters which will not rise and fall to the motion of small waves, and will not transmit them. These breakwaters are suitable for use in the shallower waters of partially protected localities.—The gases liberated on pulverising minerals—monazite: R. J. **Moss.** On reducing Norwegian monazite to powder *in vacuo* gas was obtained in the proportion of nearly 0·04 c.c. per gram of the mineral; 100 volumes of this gas contained:—hydrogen, 45·63 volumes; helium, 7·63; nitrogen, 28·93; oxygen, 7·09; carbon dioxide, 10·67. The nitrogen and oxygen being in atmospheric proportions were probably due to leakage. In addition to those gases a small quantity of water was liberated in the pulverisation of the mineral. Relatively to the helium, the quantity of hydrogen is much greater than was found in gas obtained by the same method from pitchblende.

EDINBURGH.

Royal Society, May 15.—Sir John Murray in the chair.—A new form of bolometer adapted for physiological investigation: Dr. W. **Colquhoun.** By using thin metal gratings of low resistance in a Wheatstone bridge arranged as delicately as possible, the author was able to demonstrate with it the heat produced by the beating of a frog's heart.—The magnetic quality of a Boschovichian assemblage of molecular magnets: Dr. W. **Peddie.** This paper gave a development of the theory of molecular magnetism which applies to crystals of the cubic system. The close-packed arrangement of centres was adopted, but similar treatment would apply to any other arrangement. The results were applied to the experimental data obtained by Weiss in observations on magnetite. The conclusions were:—(1) the theory is capable of giving a good account of observed phenomena; (2) in Wallerant's formula, which gives the correct mathematical relation between quantities, the quantities which he interprets as magnetisation and external force should be interpreted as internal force and magnetisation respectively. Here "internal force" means the force exerted by the group of molecular magnets. The internal action is completely represented by the quartic surface $x^4+y^4+z^4=1$.—Suggestions towards a theory of electricity based on the bubble atom: J. **Fraser.** This extension of a previous communication on the constitution of matter consists essentially of suggestions without rigid mathematical development. The treatment of conduction was of interest as suggesting a possible model of a dynamical system the properties of which simulate those of an electric conductor.—The Nudibranchiata of the Scottish National Antarctic Expedition: Sir Charles **Eliot.** The paper contained the description of two new genera and two new species.

MANCHESTER.

Literary and Philosophical Society, April 4.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—Portion of a stem of *Sigillaria vascularis* giving off a branch with the structure of *Lepidodendron selaginoides*, thus confirming Dr. Williamson's conviction of the identity of these two Coal-measure plants: Prof. F. E. **Weiss** and J. **Lomax.**—Notes on the Wilkinsons, ironmasters: F. **Nicholson.**

April 18.—Prof. W. Boyd Dawkins, F.R.S., president, in the chair.—A new method of producing coloured diffusion bands: H. **Stansfield.** One surface of a piece of plate glass, rendered diffusive by spoiling the polish or coating it with a diffusing film of resin or butter, was fixed so as to be nearly in contact with the reflecting surface of a polished silver mirror, the surfaces being separated at the corners by a single thickness of stamp-edging. Greater dispersion of the colours is obtained in this way than by breathing on the glass surface of a silvered mirror, as the air film can be made much thinner than the mirror glass.—Notes on chlorine: C. H. **Burgess** and D. L. **Chapman.**

May 2.—On some constituents of Manchester soot: Prof. E. **Knecht.** The author pointed out at the outset that smoke and soot did not consist of carbon alone, as was popularly supposed, and went on to show that the soot obtained from the "fat" coal which is used in the Manchester district contains at least 50 per cent. of substances other than carbon. A variety of interesting products were shown which had been isolated from an average sample of household soot collected in Manchester. These included snow-white samples of ammonium chloride, ammonium sulphate, calcium sulphate, and a beautifully crystallised paraffin hydrocarbon which was similar in properties and composition to one which was known to exist in bees' wax. The amount of heavy hydrocarbon oils contained in our household soot was found to be no less than 13 per cent. From the brown coloured acid constituents the author had prepared a dye-stuff which was capable of producing absolutely fast shades of brown on cotton, dyed samples of which were shown. Comparative analyses of samples of soot collected in London and in Prague showed that these (especially that from Bohemian lignite) were much cleaner than the Manchester soot. After commenting on the drawbacks attendant on the presence of soot in our atmosphere, chiefly due to household fires, the lecturer expressed the opinion that no amelioration could be hoped for unless the use of more efficient fire-grates could be made compulsory.

PARIS.

Academy of Sciences, June 3.—M. Troost in the chair.—Observations on the methods employed in calorimetry, with especial reference to the determination of the heat of combustion of organic compounds: M. **Berthelot.** A polemical paper in reply to Julius Thomsen. The author strongly supports the accuracy of the results obtained by the calorimetric bomb as against the combustion under atmospheric pressure.—On the dynamics of the electron: H. **Poincaré.** A discussion of a recent paper by Lorentz on electromagnetic phenomena in a system moving with any velocity smaller than that of light.—Photographs in colour of the spectrum, negative by transmission: G. **Lippmann.** In the case of photographs on bichromatised gelatin films it has been hitherto necessary to moisten the film each time it is desired to observe the colours. By alternate treatment with solutions of potassium iodide and silver nitrate the colours become permanent and visible after drying.—The preparation and properties of the chloride and bromide of thorium: H. **Moissan** and M. **Martinsen.** The chloride of thorium was prepared by the action of well dried chlorine on metallic thorium prepared in the electric furnace. Owing to the extremely hygroscopic properties of the thorium chloride it was impossible to transfer it mechanically to a vessel for analysis, and it was therefore volatilised directly into a

glass tube in a current of dry hydrogen. The purity was determined by analysis, the melting point being found to be 720° C.—On the transmission by ticks of spirillosis and of bovine piroplasmosis: A. **Laveran** and M. **Vallée.** A specimen of the larva of *Rhipicephalus decoloratus* forwarded by M. Theiler from Pretoria, and stated by him to be the cause of the transmission of spirillosis in cattle, was allowed to act upon a healthy cow, with results entirely confirming those of M. Theiler.—The evolution of the Tertiary mammals: Charles **Depéret.**—Magnetic observations at Tananarivo: P. **Colin.** Tables are given showing the results of measurements of magnetic declination, inclination, and the horizontal component taken weekly between May, 1904, and April, 1905.—The principles of anallagmatic geometry: A. **Demoulin.**—Some new experiments on the lifting power of the helix "M. Léger" at the oceanographic museum at Monaco: M. **Léger.** The apparatus proved capable of lifting a man, together with a weight representing its motor and the petrol necessary for an experiment of one hour's duration.—A new mode of application of the Pitot-Darcy tube to the measurement of the velocity of water in pipes under pressure: H. **Bellet.** The modification suggested is the use of a two-fluid manometer, water and a liquid of density slightly greater or less than that of water; carbon bisulphide tinted with iodine gave the best results.—The magnetic properties of the simple element of pyrrhotine: Pierre **Weiss.**—On a property of the tin-aluminium, bismuth-aluminium, and magnesium-aluminium alloys: H. **Pécheux.**—The action of oxygen upon cæsium-ammonium: E. **Rengade.** The rapid oxidation of cæsium-ammonium dissolved in an excess of ammonia gives the oxides Cs_2O_2, Cs_2O_3, and Cs_2O_4, all in microscopic crystals. If the oxygen is added gradually a secondary reaction takes place, the amide and hydroxide of cæsium being formed.—Pyranic phenols: R. **Fosse** and A. **Robyn.**—On a new reagent for aconitine: E. P. **Alvarez.**—On the expansion and density of some gases at high temperatures: the application to the determination of their molecular weights: Adrien **Jacquerod** and F. Louis **Perrot.** Figures are given for air, oxygen, carbon monoxide, and carbon dioxide on the basis of the nitrogen thermometer at the melting point of gold. The molecular weights based on the density determinations at 1067° C. give for CO and CO_2 results agreeing within 1/3000th with the results of analysis; for nitrogen, the value found agrees with the atomic weight, 14·008.—Osmotic pressure in colloidal solutions: J. **Duclaux.**—On the coagulation of starch: A. **Fernbach** and J. **Wolff.**—On methæmoglobin and its fluorine combination: J. **Ville** and E. **Derrien.** The authors maintain the accuracy of their results against the criticism of Piettre and Vila.—Protagon and the cerebrines and cerebric acid preexisting in the nervous tissue: N. A. **Barbieri.** The author regards the protagon of Liebricht as a mixture of cerebrin and the cerebric acid of Fremy.—On the effects of annular decortication: Leclerc **du Sablon.**—On the results obtained by the observation of arable earths in thin plate: A. **Delage** and H. **Lagatu.** A reply to various criticisms on an earlier paper.—Researches on the ethnography of the Dravidians: Louis **Lapique.**—On the evolutions of the sexual forms in the soft-water Nereids: Ch. **Gravier.**—The simultaneous contrast of colours: A. **Polack.** The phenomenon of the simultaneous contrast of colours appears even when accidental images by the movement of the eye are completely eliminated. Under these conditions the effect of contrast depends on the state of accommodation of the eye.—On the heats of combustion and chemical composition of the nervous and muscular tissues of the guinea-pig, considered as a function of the age of the animal: J. **Tribot.**—On a new method of protection against the Röntgen rays: J. **Bergonié.** The principle of the method consists in placing the whole of the arrangements about the patient above the horizontal plane prolonging the anti-kathode, and below this plane the patient himself. The method has proved successful after six months' use.—On the denomination of the supposed agent in syphilis: Paul **Vuillemin.**—The presence of methane in the borings in Lorraine: Francis **Laur.**—Captive balloon ascents carried out over the sea by the Prince of Monaco in April: H. **Hergesell.**

THE CHEMISTRY OF PLANTS.

Biochemie der Pflanzen. Vol. i. By Prof. Friedrich Czapek. Pp. xv+584. (Jena: Gustav Fischer, 1905.) Price 14 marks.

THIS work forms a new type among those on physiological botany: in some degree it resembles "Die Pflanzenstoffe" of Husemann and Hilger, and "Die rohen Stoffe des Pflanzenreiches" of Wiesner; but whereas the bias of the former is pharmacological, and that of the latter economic, the subject is treated in this volume more from the chemical standpoint.

The author states that his book is not to be regarded as a treatise or handbook for students, but as a work for reference, and that he has endeavoured to show in it what results the application of chemical methods to the problems of botanical physiology have yielded.

The subject-matter is divided into three parts—a historical introduction of 19 pages; a general part of 62 pages; and a special part of 489 pages. The general part is divided into two chapters, dealing respectively with the substratum of chemical processes in the living organism, and with the processes themselves. The first chapter treats of protoplasm and its constituents, colloids, then protoplasmic structures and their biochemical import; the second of reactions from the standpoint of general chemistry, a survey of the conditions of reactions, ionic reactions in the living cell, the velocities of reactions, catalysis, the general chemistry of enzymes, cytotoxins, and similar substances being here made.

The special part is concerned with the occurrence, metabolism, and metastasis of aliphatic substances in detail. The general arrangement of this part is in the first order chemical: the first section is devoted to fats, lecithins, phytosterins, and waxes; the second to carbohydrates, commencing with the simpler sugars, and ending with the substances forming the skeletal structure of plants. In the second order the arrangement is mixed; the chapters deal in part with the taxonomic, in part with the morphological, anatomical, and histological distribution of substances, and further with the physiology of the various bodies considered.

Photosynthesis receives considerable attention, and is regarded in all aspects; in connection with it the physics and chemistry of chlorophyll are discussed at length, and other pigments are also dealt with. The treatment of the physics and chemistry of starch is also fairly extensive. An index of the subjects and authors will be given at the end of the completed work.

The general nature and structure of the book having been reviewed, passage to criticism of it will now be convenient. A work of this kind, involving the two main ideas of chemistry and plants, requires, if it is to yield its full value, so to be arranged as to enable the composition or metabolism of a plant (in so far as this is known), as well as the distribution of a substance or a process, to be ascertained with equal ease. But this is not the case with this work owing to its arrangement; the mode of treatment is analytic rather than synthetic. In "Die Pflanzenstoffe" one volume deals with the material from the chemical, the other from the taxonomic standpoint; but this method, although very convenient, necessitates duplication. The difficulty could have been here met through use of a suitable and strictly methodical arrangement, had the divisions of various orders of magnitude been formed from different standpoints, and had those which constituted each order been of similar kind and value. The end can be still attained here by aid of a copious and well-arranged index of the subject-matter.

Printers' errors are not very numerous, and occur chiefly in the earlier part of the book.

Discrepancies and slips of the pen are noticeable here and there. For example, on p. 7 Priestley is given as the discoverer of oxygen, but on p. 12 Scheele; on p. 144 *anaërobem* should be *aërobem*; *Bedeutung* on p. 434 should be *Beleuchtung*. From the structure of a sentence on p. 39 one might suppose that ethyl-ether was insoluble in water. Further, the last paragraph on p. 313 is hardly consonant with the author's apparent acceptation of Meyer's hypothesis of the structure of starch-granules on p. 312.

Since the work is one for reference, hence a compilation, and since the author has intentionally almost entirely avoided critical remarks on the subject-matter, the reviewer can only consider the selection from a critical standpoint. It may be said, on the whole, that the selection has resulted in a very representative collection of diverse opinions on controverted questions, and in many cases almost an exhaustive one. As a result of this, condensation is, in the case of many papers, extreme, and at times there is omission; but this is almost a necessary consequence of the mass of literature consulted.

One disadvantage, which is, however, common to all books of this class, is the slight indication of the relative values of the various works cited; all emerge with equal distinctness, except in so far as more space is given to some than to others; beyond this clue there is no guide to their relative worth. This is well shown in the case of the chemistry of starch and some of the pigments; a chemist or botanist who had not devoted any special attention to these substances would rise from a perusal of the epitome here given under the impression that there was only chaos.

In connection with the chemistry of starch the author does not seem to have had at hand all the works of H. T. Brown and his collaborators, G. H. Morris and J. H. Millar, or to have grasped their views quite clearly.

Enzymes are stated to be colloidal catalysors, and their colloidal state is said to be of import. In the opinion of the reviewer there is no sufficient evidence to show that any enzyme is a colloid, and, indeed, considerable reason why many should not be so. There is even no sufficient evidence that enzymes are chemical compounds; they may be essentially mixtures, or merely functions of special conditions.

In the consideration of the action of accelerators

and retarders on amylohydrolysis, there is no mention of Ford's recent work.

Cytase is stated not to occur in resting seeds, but it is present in small amounts in some.

In giving directions for the preparation of Schweizer's solvent for cellulose, the best method, that of dissolving metallic copper in ammonia through which a current of air is passed, is not mentioned.

The function of a critic is to criticise; but he is human, and hence prone to eulogise—or blame. In this case the reviewer can only yield praise. The work fills a void that botanical physiologists have long felt. The wealth of material dealt with is surprising, and the expenditure of labour must have been enormous. There is very little evidence of partiality, whether national or of other kind. The compass of the work is wide, and it is thoroughly up to date.

The reviewer was especially pleased with the general part. For the first time in a botanical work adequate stress is put on the importance of colloids as such, and on the necessity of knowledge of their nature for progress in physiology; and for the first time the principles of general chemistry are given the position due to them in a work of this class. To Prof. Czapek for having done this all botanical physiologists must remain indebted.

In the opinion of the reviewer the value of the work would have been enhanced by incorporation in it of curves illustrating the various processes described, and by citation of mathematical expressions wherever they have been proved or found to be applicable.

If the work should run through subsequent editions, as is most likely, it would certainly be best for different authors to be delegated for various parts, since with the rapid accumulation of material it will soon be impossible for a single author to deal adequately with a work of such dimensions.

F. ESCOMBE.

THE ELECTROMAGNETIC THEORY OF INERTIA.

(1) *Mathematische Einführung in die Elektronentheorie.* By Dr. A. H. Bucherer. Pp. 148. (Leipzig and Berlin: Teubner, 1904.) Price 3.20 marks.

(2) *Experimentelle Elektrizitätslehre.* By Dr. H. Starke. Pp. xiv+422. (Leipzig and Berlin: Teubner, 1904.) Price 6 marks.

(3) *Leitfaden der Physik für die oberen Klassen der Realanstalten.* By Dr. F. Bremer. Pp. viii+294. (Leipzig and Berlin: Teubner, 1904.) Price 3.20 marks.

(1) THE property of matter which has always been regarded as most fundamental is "inertia." This property is adopted as the measure of quantity of matter in dynamics, and the nearest approach to a complete explanation of a physical phenomenon is generally supposed to have been reached when the phenomenon has been shown to be due to the motion of particles possessing inertia. We may say, in fact, that the tendency of nineteenth century physics was to give a purely dynamical explanation of everything. A striking example of this tendency is Maxwell's dynamical theory of the electromagnetic field.

In 1881 it was shown by Prof. J. J. Thomson that a particle charged with electricity possesses some inertia due to its electric charge in addition to the ordinary inertia of the particle. As the result of Kaufmann's measurements, we now know that all the inertia of an electron is of this electromagnetic kind. It is now further suggested that all matter is composed of electrons, so that all inertia is electromagnetic. Density, according to this view, is simply number of electrons per unit volume. Electromagnetic inertia, that is, all inertia, is due to the energy of the magnetic field produced by the moving charge of electricity. The energy of this magnetic field resides in the ether. According to Maxwell's dynamical theory, the electromagnetic energy of the ether is due to motion of parts of the ether, these parts possessing inertia. But the only kind of inertia which we really know is the inertia of matter, which is due to the electromagnetic action of the electrons of which matter is made up. If inertia is due to electrons, then if we ascribe to parts of the ether the property of inertia we ought to say that the ether contains so many electrons per unit volume. But the free ether is not supposed to contain any electrons; in fact, if we explain inertia by the energy of the magnetic fields produced by moving charges, then evidently to explain this energy by inertia in the ether is merely to argue in a circle. The position is, then, that inertia is explained in terms of the electromagnetic field, and that now some explanation of this field is required not involving inertia at all. So far, no such explanation has been offered. Larmor has suggested that the ether has an enormous density or inertia per unit volume, and that it moves along the lines of magnetic force. This explanation must evidently be abandoned if matter is regarded as made up of electrons having only electromagnetic energy, or else we must say that the ether has a sort of inertia, not the same as the inertia of matter, but like the kind of inertia matter was supposed to have before the electromagnetic theory of inertia was put forward.

To say this, however, is merely to ascribe to the ether a property the definition of which is that it explains what it is required to explain; it is, in fact, merely the old process of "explaining" a thing by inventing a name for its explanation. The properties of the ether, then, expressed by Maxwell's system of equations are at present without any explanation, but they have taken the place of inertia as the fundamental thing in terms of which phenomena are to be explained. In these circumstances the appearance of Dr. Bucherer's small volume on "Elektronentheorie" is exceedingly opportune. It contains a concise and readable account of Lorentz's splendid theory and of the electromagnetic theory of inertia. The introduction gives a short account of the properties of kathode rays and radium radiation, which, of course, are the properties of electrons on which the electronentheorie is based. Chapters i. and ii. contain a short account of Lorentz's theory for bodies at rest, and chapters

iii. to v. the theory for moving charges, vector analysis being used throughout. The remaining chapters deal with radio-activity, rotating charges, radiation from electrons, the Zeeman effect, the theory of Röntgen rays, aberration, and dispersion.

The mathematical theory of the properties of electrons appears to be well and clearly dealt with on the whole, and the author has managed to compress a great deal of information into a small space. English readers will probably feel that sufficient credit is not given to some English physicists to whom the initiation of the whole theory is really due. The parts of the book dealing with experimental facts and the theory of things outside the electromagnetic theory are rather superficial and sometimes erroneous. For example, it is stated that the radio-activity of radium emanation diminishes very rapidly with rising temperature, and that this can be deduced thermodynamically from the large amount of energy evolved. This glaring error shows conclusively that the author's acquaintance with the literature of radio-activity is of the slightest. The book will no doubt be welcomed by many anxious to learn about the new views on inertia and matter, and to such it should prove useful.

(2) Dr. H. Starke's book on experimental electricity and magnetism contains a very up-to-date and excellent elementary account of the subject. The explanations of many of the experiments described seem scarcely full enough to enable students actually to work from them, but it is evidently not intended that they should do so without further help. Many good diagrams of modern forms of apparatus are given.

(3) Dr. F. Bremer's book on physics for the upper classes in schools is a rather bad type of school text-book in which it is sought to make things suitable for school children by giving very short and scrappy accounts of everything. It looks like a book which might be useful to a student with a very good memory in cramming for an elementary examination in physics. He might get through the examination, but he would have learnt nothing worth knowing.

HAROLD A. WILSON.

A BOTANIST'S RECREATIONS ON THE RIVIERA.

Streifzüge an der Riviera. By Eduard Strasburger. Revised edition, with 87 coloured illustrations by Louise Reusch. Pp. xxvi+480. (Jena: Gustav Fischer, 1904.) Price 10 marks.

THE Riviera has of recent years become regarded as the playground of wealthy people whose only idea of enjoyment consists in spending hours in the unhealthy atmosphere of the casino at Monte Carlo, raising dust with a motor-car, dining at separate tables, or sitting in an hotel lounge. But such people see nothing of the *real* Riviera, with its wealth of wild flowers, its charming rock villages perched on heights, its olive, orange, and lemon groves, and its torrent beds up which one scrambles from rock to rock, passing a succession of pretty pictures each prettier than the previous one. On first reading Prof. Strasburger's book, the reviewer formed the impression that the descriptions were too prosaic and wanting in sunshine. It cannot be said that the author has succeeded in giving that warmth of colour to his account which characterises Mr. Casey's charming book. But since that impression was formed the present writer re-visited the Riviera, and the feature which he most noticed was how exactly every minute detail tallied with Prof. Strasburger's descriptions. The information contained in this book is just what is wanted to make a visit to the "Côte d'Azur" both enjoyable and instructive.

A large proportion of the text is taken up with historical accounts of the various cultivated plants and trees growing in the district. The most characteristic vegetation of the lower valleys—the vine, orange, lemon, olive, fig, cypress, and palm—is largely the result of "alien immigration." Before the hillsides were carefully terraced and cultivated they were overgrown with small scrub or "maquis" (Italian "macchia") consisting of pines, rosemary, myrtle, tree heath, three species of cistus, mastic, juniper, the characteristic spiked lavender (*Lavandula stoechas*), the remarkable spiny euphorbia (*E. spinosa*), and a number of other plants too numerous to mention. The aromatic perfume of many of these plants is one of the most salient features of the "maquis." In Prof. Strasburger's description of this characteristic undergrowth, the word "Duft" (perfume) occurs over and over again. It is only after walking through such vegetation that one realises that this very repetition makes the description all the more accurate and realistic, and readers of the book will do well to bear in mind the fact that each occurrence of the word usually refers to a different scent. Prof. Strasburger's descriptions of the "maquis" mostly refer to Antibes, where a considerable area of this primitive vegetation still remains untouched. In many places along the coast the "maquis" is being rapidly cut down to make room for unlovely vineyards, and the face of the country is being made less beautiful.

Considerable space is devoted to a description of the gardens at La Mortola, and the scent manufactories at Grasse also occupy many pages. In reading these descriptions one cannot help regarding the author somewhat in the light of a walking encyclopædia. He gives long digressions on the manufacture of chemical perfumes in connection with Grasse, and he makes his account of Sir Thomas Hanbury's garden the opportunity for giving much historical information about many economic plants such as the tea, coffee, and cocoa plants the sugar-cane—and, thence, the introduction of beet-sugar, the ebony and the camphor tree —which can hardly be regarded as the *characteristic* vegetation of the district. On the other hand, several interesting features are mentioned which a casual visitor might overlook. The characteristic flora of Hyères and the comparative absence of dust in the Esterel mountains are associated with the remarkable difference of geological formation as compared with the more frequented and fashionable but dustier winter stations in the limestone districts. The nightly concert of green frogs to which the author alludes is a sound which brings the Riviera vividly back to everyone who has heard it.

On the whole, Prof. Strasburger seems to have devoted most of his attention to studying the plants

growing in gardens and near the towns, and he does not describe many scrambles up into the distant mountains. But of the wild flowers to be found on the hillsides or up the torrent beds no better guide could be afforded than the beautiful series of coloured illustrations distributed throughout the text. It is possibly a pity that the figures are mostly printed with black outlines, and it might be thought preferable to have them printed on plates instead of mixed up with the letterpress. In addition to flowering plants, a number of the characteristic seaweeds have also been illustrated, and several charming little sketches of Riviera coast scenery, in the form of headings to the descriptions of the five different holidays spent by Prof. Strasburger on the Riviera, are a welcome addition. All these illustrations have been tastefully drawn and coloured by Fraülein Reusch.

G. H BRYAN.

INTERNATIONAL PHYSICS.

Recueil d'Expériences élementaires de Physique. By Henri Abraham. Part ii. Pp. xii+454. (Paris: Gauthier-Villars, 1904.) Price 6.25 francs.

WE have already reviewed the first part of this collection of physical experiments, which has been gathered together under the auspices of the French Physical Society. A large number of physicists from all over the world have participated in the collaboration by sending both descriptions of experiments and bibliographical references, and the editor's work has consisted in giving as much homogeneity as possible to the products of this multiple collaboration.

The present and concluding part embraces the subjects of acoustics, optics, electricity and magnetism. On the whole, the experiments in this part are of a more difficult and elaborate kind than those previously described. This is to some extent, no doubt, due to the nature of the subjects treated. General manipulation and mechanics required less reference to be made to complicated and expensive apparatus than the subjects considered here. As a consequence of this the private student who has no access to a properly equipped laboratory will find much greater difficulties in his way. He will still find a field for work in acoustics and light. With a few springs and wires a considerable amount may be done in sound; and, in the experiments on light, homely articles like pins and champagne bottles are freely made use of. But in electricity and magnetism he must be prepared for greater outlay in apparatus. We lay stress on this point, because in our previous reference we recommended the book strongly to the private student with a taste for practical mechanics.

The present part will be found of greatest utility to the schoolmaster eager for hints in the arrangement of class and lecture experiments. One special feature in the descriptions is that in most cases the dimensions of the apparatus which have been found to work well are given. This will certainly save a teacher a great deal of time, which otherwise he would need to spend in experimenting himself in order to discover the suitable size and shape of his apparatus. We do not hesitate to say, however, that time so spent is never lost, and if in the busy workaday world of the teacher some means for saving of time is essential, it has its disadvantages.

It is usually only by the somewhat laborious method of trial and error that one learns the conditions necessary for success.

There does not seem to be much in the volume which is absolutely novel as regards style of experiment. The aim, obviously, has been to describe as simple experiments as possible illustrative of all the common laws of physics. This description is in all cases very brief. There is no introduction of theoretical considerations; nor is there any attempt to make the subject attractive to a general reader. A figure, a short account of the construction and mode of using the apparatus—that is all.

In some cases the suggestions are open to criticism in minor details. Thus, vibrating springs, which ought to be attached to a fairly solid support, are shown screwed to a slender skeleton wooden box. But in the main the suggestions seem excellent, and there are few teachers who will be able to learn nothing from them.

The diagrams are not always clear; nor are they such as to give the book an attractive appearance.

Briefly, the collection is meant for the teacher and not for the student. To the former it is commended, with the hope that he will be able to give life to these somewhat dry bones by instilling his own individuality into them.

LIGHT AND HEALTH.

The Effects of Tropical Light on White Men. By Major Charles E. Woodruff. Pp. vii+358. (London and New York: Rebman, Ltd., 1905.) Price 10s. 6d. net.

THE title of this book gives little idea of the enormous field traversed by the author, or of the amazing conclusions at which he has arrived. We understand that the work is intended for laymen as well as for medical readers, and particularly for Americans about to reside in the Philippines. No exception can be taken to the advice given by Dr. Woodruff in his concluding chapters. The necessity for opaque white clothing, and of sufficient protection to the head; the paramount importance of the siesta, and of avoidance of work and social functions in the middle of the day are recognised by Europeans living in the tropics. The suggestions as to the selection of suitable recruits for the army in the Philippines are admirable.

But it is impossible to accept many of Dr. Woodruff's deductions from the scientific observations which he so largely quotes. Even if we take it for granted that the "death-rate of a place is proportional to its sunshine and inversely proportional to its latitude, other factors being eliminated," does it follow that the death-rate is dependent upon the amount of light, and have the other climatic conditions, and especially the parasitic insect life, no influence? Dr. Woodruff would have us believe so. He informs us that light is like alcohol, tea, coffee, and other stimulants. In moderation, it is beneficial; in excess, it is harmful. "We can do without it, but our metabolism is too sluggish or defective if we do not get it." Excess of

light, we are told, produces first stimulation and then depression, neurasthenia and even loss of memory. To protect us from these terrible ills we require a skin so highly pigmented that the sun's rays cannot influence our delicate nervous organisation. The want of a sufficiency of pigment in the skin, Dr. Woodruff informs us, has played an important part in the history of the world. The decline and fall of the Roman Empire and the decay of Greece were, in his opinion, due to the fact that the military forces of these powers were largely recruited from the northern blonde races. These dominating blondes, bred under cloudy skies, were reduced to impotence because their skins were insufficiently pigmented to resist the baleful influence of the bright sun of the Mediterranean. Light, and not luxury, was responsible. It is not surprising to learn that the conduct of the schoolboys of New York is worse on a bright June day than on a cloudy day in winter, but we should have thought that the author's reminiscences of his own school days would have suggested that there were other more probable causes than the irritating effect of the chemical rays of light upon the schoolboy's nervous system.

It is difficult to criticise an author who, in considering the experimental work of Ferni, whose opinion differs from his own, says, "it seems certain that he has been misquoted, and that the fact is the reverse of what he is alleged to have said." It is surely usual in a scientific treatise to verify references, but here, as elsewhere, Dr. Woodruff appears to have been rather hurried.

While admiring the author's industry and his courage in advancing his contentions, we cannot but consider many of his conclusions unwarranted. With the remark that it is a pity that our slum babies cannot undergo such "torture," we cannot forbear quoting the following statement of Dr. Woodruff:—

"We moderns of the intelligent classes alone violate the mother's instinct to hide away in the dark with her baby, and we ruthlessly thrust it out into the sun's rays, actually strapping the poor little sufferers into their carriages and torturing them with the direct rays of the sun pouring down into their faces."

OUR BOOK SHELF.

Handbuch der Heidekultur. By Dr. P. Graebner. Pp. viii+296. (Leipzig: W. Engelmann, 1904.) Price 9s. net.

THE German word "heide," like the English "heath," is applied to very different types of vegetation. In the narrowest acceptation it signifies a district covered with dwarf shrubs where ling or heather predominates, and such a formation is not uncommonly associated with loose, sandy soil. But in north Germany "heide" implies a wood, usually a pine wood, and the same conception attaches to it in other parts of Germany, as, for instance, the Dresdener Heide. Heath is therefore not a formation according to the ecological use of the word, but is applied to land where certain physical conditions prevail, and covers not only stretches of open woodland, but also grass and other moors, and may even be extended to peats and bogs. One feature common to these different formations is the presence of humus, and this is included in the definition given by Ramann.

The suggestive views as to the formation of heaths advanced by Dr. Graebner in 1901 have become widely known, and have received very general acceptance. Heaths or moors may develop on sands or under water, but in north Germany, at any rate, and not improbably in other countries, much of the heathland has taken the place of forests. Opinions differ as to the causes which have brought about the change. Borggreve and Krause have attributed the disappearance of forests to destruction by animals, but Graebner attaches more importance to continual draining of salts into the lower layers by percolating water. Another factor, which has not been sufficiently emphasised by Graebner, is the action of those bacteria which give rise to humus in the absence of air. Want of air no less than impoverishment of the soil plays its part.

Although the book is written for the practical man, Dr. Graebner has included a certain amount of purely scientific matter where it has a bearing on economic problems, but the chapter written by Mr. O. von Bentheim is more especially concerned with practical considerations. It is evident that profitable cultivation of heath land requires not only careful and scientific farming, but in some cases success can only be attained by general cooperation of the farmers either as a society or under Government supervision. The preparation of the land for agricultural farming or for tree planting is discussed in detail; as a preliminary deep ploughing is advisable and quite necessary where moor-pan has formed. Moor-pan (Ortstein) is practically a layer of stone, which is formed when percolating water containing humates reaches layers of soil which are rich in mineral salts; the humates are precipitated, and bind the particles of soil into a stratum of stone, which as it thickens cannot be penetrated even by tree roots.

In the latter portion of the book the different formations are considered from the purely botanical standpoint according to the characteristic plants. The problems connected with the cultivation of heaths are complicated but interesting; for this reason the opinions of Dr. Graebner, who has made a careful study of the subject, are the more valuable.

I Nuovi Indirizzi e le Promesse della Odierna Antropologia. By Fabio Frassetto. Pp. 71. (Castello: C. E. S. Lapi, 1905.) Price 3 lire.

THIS little work consists of a series of four lectures which the author delivered as an introduction to his course of anthropology in the 1904–5 session of the University of Bologna, where, after a break of twenty years, he has taken up the work begun by Sergi before his removal to Rome. Appropriately enough, the first lecture of the four deals with Sergi and his principles of skull classification, and sketches very briefly the types and the deductions which Sergi draws from them—Eurasian and Eurafrican forms, and five species of pygmies—at the same time pointing out that many of these views are only provisional. Dr. Frassetto holds that just criteria of race are of the utmost importance, not only for the sociologist, which most inquirers would be prepared to admit, but also for the medical man, who will more readily diagnose the maladies which he has to treat, in proportion as racial morphology and pathology are determined with precision and at the same time it becomes possible to classify the individual patient from an anthropological point of view. If he is too sanguine in this, another point on which Dr. Frassetto insists does not seem beyond the range of practical politics; this is the development of pædagogic anthropology, which shall regulate the education of the individual child by scientific principles. Even here, however, at any rate in our own case, the problem of feeding the child and of providing it with a healthy body will probably

occupy the first place for some time to come, so far as elementary education is concerned.

The second lecture deals with the work of Maggi and the morphology of the cranial bones. This is a subject on which Dr. Frassetto has himself published some valuable studies. He would have done well to indicate in his lecture that some, at any rate, of the new views on the number of centres of ossification are based on what seems to be an unduly small collection of cases. The third lecture treats of de Giovanni and his work in clinical anthropology, which deals with a patient according to his morphological characteristics rather than as an individual. Finally, we have a sketch of the work of Lombroso on criminality and genius. Dr. Frassetto insists on the need for scientific treatment of criminals, especially those of the habitual class.

It goes without saying that in brief studies of this sort we only find the broad outlines, without qualification or hint of difficulties, and herein lies perhaps a certain danger for the unfledged anthropologist who attends the academic courses. The book is, however, readable, and offers an example to English anthropologists who wish to ii terest a larger public.

N. W. T.

Catalogue of the Lepidoptera Phalaenae in the British Museum. Vol. v. Catalogue of the Noctuidæ in the Collection of the British Museum. By Sir George F. Hampson, Bart. Pp. xvi+634; pls. lxxviii-xcv. (London: Printed by Order of the Trustees, 1905.)

WE congratulate the authorities of the British Museum and the indefatigable author on the steady progress of this important work, of which a fresh volume appears, with almost clockwork regularity, every two years. The present volume is the second devoted to the Noctuidæ, and contains the second subfamily, the Hadeninæ. These are much less showy moths than those dealt with in the first three volumes of the series, and are more subdued in their colouring; but they are perhaps more interesting to British entomologists, for the family is fairly well represented in the northern hemisphere, although in a work devoted to the moths of the whole world, British, or indeed European, species are few and far between. The work is profusely illustrated, the descriptions are full but not too lengthy, and short notices of larvæ, where known (some of which are here published for the first time), have been included. The keys to the genera and the tables of species will also be found very useful by working entomologists. A table of the phylogeny of the 78 genera into which the author divides the Hadeninæ is given on p. 2, but without comment, which we think is wise, for such tables, in the present state of our knowledge, can only be tentative; and comments on the supposed affinities of genera have often a tendency to become too dogmatic.

Synonymy cannot, of course, be given in full in a work of this character, but in the case of European species, which are most burdened with it, the necessity for further details is largely obviated by a reference to Staudinger's last catalogue; still, we think that, in the case of the few British species, Barrett's "Lepidoptera of the British Islands" might have been referred to.

We heartily commend this important book to the working entomologists of all countries. Five volumes have already appeared, but if it is ever completed it will certainly far exceed in bulk the twenty-seven volumes of the "British Museum Catalogue of Birds." Hitherto it has been wholly the work of one man, and we hope that when he finally lays down his pen, a very large proportion of the gigantic task of describing the moths of the world will have been accomplished by his hands.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Spinthariscope and Retinal Excitability.

I HAVE recently been making a series of observations upon retinal excitability, and have used, among other test stimuli, the well known flashing scintillations of a pocket spinthariscope. The special value of the instrument in this connection is the subminimal or minimal intensity of the retinal excitation judged by the disappearance or appearance of visual sensation. The method used by physiologists for ascertaining whether any given condition alters the excitability of a tissue is that of stimulating periodically the tissue by subminimal or minimal exciting agencies under constant conditions and then changing one of these conditions; if, as the result of such change, the subminimal or inadequate stimulus becomes adequate, the excitability of the tissue has been raised by the change; if, on the other hand, the minimal or adequate stimulus becomes inadequate, then the excitability of the tissue has been lowered by the change.

It is well known that with the ordinary pocket spinthariscope no luminous effects are seen unless the eye has been rendered sufficiently sensitive by some minutes' darkness; this is especially the case during the daytime, the effects at night being almost instantaneously visible. The stimulation of the retina by the scintillating flashes is thus of the minimal order, and becomes subminimal when the eye is exposed to daylight.

It is thus possible to place the eye under different conditions, and to determine by means of the visibility of the flashes in the spinthariscope whether the retinal excitability has been raised or lowered; the method has the merit of great simplicity, all that is necessary being to go into a dark room and immediately look through the instrument; the time necessary for the appearance of the first visible luminosity and for the full appearance of the flashes is longer the lower the general excitability of the retina.

A further point of physiological interest is brought out by simple experiments along these lines. It is well known that when the eyes at night look at groups of stars, faint groups not in the direct line of vision are distinctly seen which disappear when the gaze is directed towards them. There is an accumulating mass of evidence that this familiar experience is the sensory aspect of a modified condition of the retina, the modification consisting in an augmented excitability of the peripheral portions of the retina. It appears probable that such peripheral augmented excitability is localised particularly in the outer segments of one set of retinal elements, the rods, which contain the visual purple discovered by Kühne. The rods are extremely numerous in the peripheral region, and constitute the sole elements in nocturnal birds such as the owl. The visual purple of the rods is blanched by light, especially by the more actinic rays, but the blanching disappears with darkness, and this re-constitution of the substance is associated with the presence of the choroidal pigment. There is thus an adaptation process which renders the dark-adapted eye more excitable than it otherwise would be, and this augmented excitability is especially prominent in that part of the retina which contains large' quantities of rods, viz. the peripheral portions. The specialised elements of the central part of the retina (macula lutea) consist in man almost entirely of cones; it is undoubted that in daylight this part is the most excitable region, and that it possesses to a remarkable degree the capacity of localised response, thus enabling two sources of light to be discriminated as distinct when so near together that they subtend an extremely small angle. At night, or with the dark-adapted eye, the whole condition is modified, and the peripheral part of the retina has its excitability augmented more than the central part, so that sources of light of subminimal intensity for the latter are adequate to excite the former; these facts are readily demonstrable by means of the spinthariscope.

Thus if in the day time the observer takes the spin-

thariscope into a dark room he will notice that the first visible effect is a slight general luminosity when the visual gaze is directed down the optical centre of the little tube. If, however, the gaze is shifted to the side of the tube, the whole spinthariscopic display with its scintillating flashes becomes distinctly visible. On opening the door of the dark room and going into the daylight the subsidence of the central and peripheral responses can be followed, whilst on returning to the dark room the re-appearance, first peripheral and then central, can be observed with great distinctness. The essential difference between the light-adapted eye and the dark-adapted eye is thus readily demonstrable, and the rapidity, as well as the efficiency, of such adaptations can be easily followed if the eye is subjected to appropriate periods of darkness and of light.

It is evident that with such a minimal test the influence of a large number of other conditions may be investigated. Without going into these, I may mention one of considerable interest. If the observing eye is kept in the dark-adapted stage by means of a removable bandage, whilst the other eye is subjected to periods of darkness followed by daylight illumination, then the visible effects in the dark room still indicate modification. In my own case illumination of one eye causes a distinct lowering of the retinal excitability of the other one, this being especially characteristic of the peripheral region of the retina. In this connection it should be remembered that the pigment cells alter in the frog as the result of illumination, and that this alteration has been shown by Engelmann and v. Gendre to occur when, the eyes being kept dark, the skin of the frog is illuminated; one eye thus influences the other. The spinthariscope with its constant minimal excitation affords a means of demonstrating this consensual effect. It appears to me that with slight modifications the instrument may become of considerable clinical value. For clinical use it has the merit of being portable and easily used. It furnishes, with no apparent decrease through time, use, &c., a constant and continually recurring stimulus which is of threshold exciting value. It can be easily applied to either the central or peripheral portions of the visual field, and gives indications which are comparable with each other, and are only altered through alterations in retinal excitability. No doubt it can be modified in form so as to be still more useful from the clinical point of view, but even in the form in which, as a scientific toy, it is now presented, its use will show whether the central or peripheral retinal excitability is abnormal, and I anticipate that before any changes can be observed with the ophthalmoscope, it will be possible by its means to ascertain alterations in retinal excitability in the early stages of disease. FRANCIS GOTCH.

Physiological Laboratory, Oxford, June 10.

Solar Changes and Weather.

IN NATURE of June 8 (p. 129) Dr. Lockyer says:—"*Up to the present time*" (italics mine) "those who have been attempting to explain variations of weather on the supposition of solar changes have been looking for the effect of solar action as either increasing or decreasing simultaneously the rainfall over the whole earth."

This is, I think, somewhat inaccurate. The possibility of a given phase of solar change being causally related to opposite weather conditions in different regions has been recognised by many, if I mistake not, for a considerable time. I might instance M. Angot, who expressly affirms it in his "Traité de Météorologie," published a few years ago; and what he there says on the subject indicates a certain currency of the idea previously, of which (no doubt increasing) currency back volumes of NATURE and other serials give evidence. The idea of a barometric see-saw in Asiatic regions, connected with sun-spots, was discussed in NATURE so far back as the 'seventies, if I remember rightly. A. B. M.

WITH regard to Mr. A. B. M.'s remarks above, may I, in the first place, mention that I am familiar with some of the meteorological researches of such high authorities as Chambers, Meldrum, Blandford, Eliot, Hann, Angot, &c., but still there seems to be a tendency for the solar changes, that is, changes indicated by sun-spots, to be considered as affecting the whole earth simultaneously at any one epoch. It would have been more correct for me to have written "Up to the present time many of those who have, &c.," than "Up to the present time those who have, &c.," but at the time of writing I was considering more the generally conceived impression as to the relation between sun-spots and meteorological changes than the results of investigation of any particular region on the earth's surface.

To take a case in point, two years ago M. Charles Nordmann (*Comptes rendus*, vol. cxxxvi., p. 1047, May 4, 1903) communicated to the Paris Academy of Sciences a paper entitled "La Périod des Taches solaires et les Variations des Températures moyennes annuelles de la Terre." This title implied that the solar changes were affecting the whole earth similarly, but the investigation was only restricted to the equatorial regions, where the conditions are most favourable for such an inquiry. Further, I am inclined to think that the result he obtained will be found to apply only to that portion of this equatorial belt lying between about longitude 40° E. and 140° E. The reason for this is that out of the thirteen stations in all which he employed, eight were included in this region (five stations of which were given double the weight of the others), and only five were situated in the other part of the belt. If it were possible to include more stations in the western hemisphere, the relation between temperature and sun-spots which he obtained might probably be reversed. WILLIAM J. S. LOCKYER.

Solar Physics Observatory, South Kensington.

Fictitious Problems in Mathematics.

ON reference to § 156 of "Rigid Dynamics," it will be seen that the definition there given is identical with that contained in Dr. Routh's letter of May 25, with the exception that the words "When the bodies . . ." occur in my edition instead of "When bodies . . . ." No statement is made as to what is meant by saying that *a body* is perfectly rough, and it is against this latter mode of expression that my attack is directed. For this reason it may be maintained that the definition given in the book in which the problem occurs is inapplicable to the problem as at present worded. Otherwise we appear to be dealing with a plank such that in the given circumstances, one of which is resting on a smooth table, the amount of friction necessary to prevent sliding can certainly be called into play, and this is apparently inconsistent with Dr. Routh's interpretation.

I would challenge your correspondent, "An Average College Don," to point to any text-book containing an explicit definition of *a* perfectly rough *body* (not *bodies*); also *a* perfectly smooth *body*. If he succeeds, I anticipate no difficulty in furnishing him with examples of questions which are either inconsistent with his definition, are ambiguously worded, or are open to some equally serious objection. G. H. BRYAN.

History of a White Rhinoceros Skull.

THE interesting specimen of the skull of the white rhinoceros (*R. simus*) referred to by Prof. H. F. Osborn, of the American Museum of Natural History, New York, in NATURE of June 8 (p. 127), was, thanks to the kindness of Mr. Graham, carefully examined by me before its sale. Its chief interest lay in the fact that the horns had never been detached, and consequently showed the true position of the nasal horn in this species; it was at right angles to the downward sloping surface of the nasal bones, thus bringing it into a most efficient position for attack.

There is a fine skull of this species in which the horns have been placed in their true position; it is numbered 2154 in the osteological series of the Museum of the Royal College of Surgeons. The animal was shot by Gordon Cumming.

The length of the nasal horn is 860 mm. (34 inches). C. STEWART.

The Romance of the Nitrogen Atom.

WITH reference to the interesting letter by Dr. Irving in NATURE of June 15 on "The Romance of the Nitrogen Atom," I should like to point out that ammonia is not so stable as is sometimes imagined. I have shown recently not only that ammonia decomposes slowly at a temperature of about 700° C., but that the decomposition is *irreversible* (*Proc. Roy. Soc.*, June), so that it will proceed until no ammonia remains. The rate of decomposition decreases rapidly with temperature, but it appears probable that even at the ordinary temperature of the air the decomposition must still proceed, although with excessive slowness. A mixture of nitrogen, hydrogen, and ammonia would thus appear to be in "false equilibrium," in the same way as a mixture of hydrogen, oxygen, and water vapour, but in the opposite sense. The "silent discharge" will decompose as well as synthesise ammonia, and brings about a state of equilibrium. Sparking has also the same effect. In these cases the equilibrium is a true one, so long as the experimental conditions remain unaltered, and it ensues when the rates of formation and decomposition of the ammonia are equal.

Notes on the Habits of Testacella.

UNDER the above heading in NATURE, vol. xxxiv. p. 617 (October 28, 1886), Prof. E. B. Poulton recorded the capture of twenty-two specimens of this rare slug upon a wall in Oxford. On that occasion there had been exceptionally heavy rains, and it was suggested that the animals had been driven out of their usual habitat, the earth, as it became sodden with moisture. I am in a position to confirm the accuracy of this suggestion. Last evening I captured five specimens of *Testacella haliotidea* upon a stone wall near Charterhouse. The slugs were apparently crawling out of the ivy which thickly clothes the top of the wall, and were making their way back to the earth. During the previous eight days no less than 3·80 inches of rain fell at this place. It seems probable that the slugs had taken refuge in the dense shelter of the ivy while the soil was unfit for them, and that on the return of hot, dry weather were once again seeking their subterranean quarters.

OSWALD H. LATTER.

Researches on Ovulation.

I SHOULD be greatly obliged if you would allow me to state in your Journal that the paragraph on "ovulation" in relation to œstrus on p. 517 of my text-book on the "Vertebrata," which was issued in March last, contains references to discoveries which were at that time unpublished, and that by inadvertence I omitted to direct attention to this. The information was supplied to me by Mr. Walter Heape. The facts relating to rabbits were discovered by him, those relating to ferrets and dogs by Mr. F. H. A. Marshall. These observations, with others, have recently been separately communicated to the Royal Society for publication in the Proceedings.

A. SEDGWICK.

ABORIGINAL METHODS OF DETERMINING THE SEASONS.

AN important and timely confirmation of the astronomical significance attached to the stone circles of Britain, and to the pyramids and temples of Egypt, comes from the Far East. From an interesting paper (*Journal of the Asiatic Society*, Straits Branch, January) by Dr. Charles Hose, who has made a special study of the subject, we learn that the natives of Borneo are at the present day using just the same general principles in determining the advent of their agricultural seasons as were used by the early Britons and the ancient Egyptians between one and two thousand years B.C. It will be remembered that, in Greece, Mr. Penrose observed (see NATURE, April 6) that the Hecatompedon and the older Erechtheum, built about 1405 B.C. and 2020 B.C. respectively, were oriented to the cluster of the Pleiades at its heliacal rising on May morning. In Egypt, Sir Norman Lockyer found that the same asterism, as the deity Nit-Isis, was probably employed as the warning star for sunrise at the vernal equinox ("Dawn of Astronomy," 1894, p. 388).

Although in Great Britain there are a great number of stone circles, their astronomical significance has, until quite recently, not been satisfactorily understood. However, the recognition of Stonehenge as a solstitial temple (*Proc. Roy. Soc.*, vol. lxix. pp. 137–147) led to an inquiry into their possible character as observatories, used by priest-astronomers to determine the advent of the seed-time and other festivals, and the investigation met with gratifying results at the outset. In the case of "The Hurlers," a group of three stone circles situated near Liskeard, in Cornwall, *prima facie* evidence was found that they were arranged in their present positions, and the stones around them placed in accordance, so that the officiating priesthood could announce to the people the arrival of the crucial seasons in the agricultural year. Among the stones used as azimuth marks at "The Hurlers," there is one with an amplitude of E. 11° N., which would mark the exact heliacal rising of the Pleiades on May morning about the year 1600 B.C. (*Proc. Roy. Soc.*, March 30). In addition to the Pleiades, it has been found that the belt of Orion was frequently used as the warning sign.

Now we learn from Dr. Hose's researches that, at the present time, the natives of Borneo, more especially the Dyaks, are using the same stars in much the same way to determine the season of the year ordained by the local meteorological conditions as the time for the preparation of the ground on which they hope to grow their food supply for the ensuing twelvemonth. During the semester October to April the prevailing wind in Borneo is from the north-east, and brings rain with it; during the other six months of the year the direction of the prevalent wind is changed, but it brings none of the month-to-month variations of conditions which in lieu of more refined knowledge would lead the agriculturist of the temperate zones to a more or less approximate knowledge of the season.

In Egypt it was the advent of the Nile flood which fixed the seed-time, and for which the celestial heralds were observed; in Britain it was, as it is now, the advent of the warm, sunny weather that was the matter of importance; in Borneo it is the commencement of the driest season that has to be recognised, because the land which is to be cultivated is overgrown by jungle or forest, and, before seed may be sown thereon, a clearance must be effected. Like the Malayans, the Dyak might use the moon as his indicator, but then, like the Malayans, he would probably get about eleven days wrong every year, a serious matter where the dry season is of short duration. The variation of the length of the day is too small in the tropics to give a definite cue as to the commencement of any special season. Consequently, the Dyaks and many of the smaller neighbouring tribes have recourse to the stars, and the stars chosen as the heralds are the Pleiades ("bintang banyak") and Orion's belt ("bintang tiga"). The native names are borrowed from the Malays, and this probably indicates that the similar use of these stars is not totally unknown among the latter. The alternative expression used by the Dyaks in naming the Pleiades is "Apai andau," meaning "the father of the day," probably so called because it is the heliacal rising of them that the natives watch for before commencing their clearing process. In Borneo it is, at present, merely an observation of the Pleiades

themselves that is made; the subsequent sunrise has no urgent interest for them; but in Egypt and Britain the stars were simply the heralds of the greater luminary for which the religious sacrifice had to be prepared by the priests.

The method of making the determination is as follows:—The surrounding terrestrial phenomena suggest the approach of the dry season, and two men are then sent into the jungle—which probably means any open space with a clear horizon—to await the celestial sign. After watching for a few nights, may be a month, the Pleiades are seen on the horizon just before the light of the rising sun overcomes that of the stars. Then the messenger-astronomers return to their village and announce the fact, and the work on the forest is commenced. Should the tribe have been so misled by the workings of terrestrial nature as to delay the making of the observation until Orion's belt rises before daylight, it means that they must work "double-shift" in order to get their ground cleared in time for the vegetable matter to dry thoroughly ere the season for burning it comes round. After this recognition of the season the interest of the tribe in celestial phenomena becomes dormant until the services of the latter are again required. Not until the Pleiades reach the zenith before sunrise do they consider it advisable to set fire to the refuse, for unless the latter has had enough time to dry thoroughly it will not be completely consumed, and the ground will be of no use for rice-growing.

With the neighbouring tribes, the Kenyahs and the Kayans, the method of determining the seasons is rather more scientific, exhibiting an advanced state of knowledge. These people are acquainted with the various phenomena attending the apparent diurnal and annual movements of the sun. They know that the noon shadow is the shortest, and that it always lies in the same straight line, sometimes to the north, sometimes to the south. Consequently, they utilise this knowledge by measuring either the length of the shadow cast by a gnomon set up vertically on levelled ground, or else the length of a beam of sunlight projected through a small hole in the roof of a hut upon a plank, laid horizontally on the floor by packing it up until round discs will not roll when placed on edge on its surface. The shadow, or beam of light, is measured by means of a stick, on which there are a series of notches. The distance of each notch from the end of the stick represents the length of shadow which experience, tinged, maybe, with superstition, has taught these people to recognise as favourable, or the reverse, for the prosecution of their various agricultural operations. The stick, known as "asa do," is carefully preserved in the keeping of an older member of the tribe, duly elected to this office on account of his superior wisdom and his incapacity for more strenuous manual labour, and it is he who watches that the beam is not measured obliquely, and announces the advent of the favourable season for sowing operations to commence.

A striking phase of the question, showing how limited is the original knowledge, possibly appears in the selection of the Pleiades and Orion's belt as the "warners." Why should these two groups be selected by so many different tribes in so many widely separated ages? A plausible explanation seems to be that their forms are instantly recognisable. Whilst the aboriginal watcher would probably not be able to recognise the isolated, though bright, stars of the large constellations, especially if, as is the case with the Dyaks, no azimuth marks were employed, he could not possibly confuse either of these with any other group of stars.

WILLIAM E. ROLSTON.

THE FOURTH INTERNATIONAL ORNITHOLOGICAL CONGRESS.

THE International Ornithological Congress assembled in London on Monday, June 12, under the presidency of Dr. R. Bowdler Sharpe, and continued in session to the end of the week. The congress was instituted at Vienna in 1887 under the patronage of the Crown Prince Rudolph of Austria. The second congress was held at Buda-Pesth, and the third at Paris in 1901, so that the London congress was the fourth of the series. It was well attended by both British and foreign ornithologists—to the number of rather more than 300. They commenced their work on June 12 by an informal meeting at the Imperial Institute, South Kensington, which was the headquarters of the congress during its session.

The British ornithologists were well represented by Dr. Hartert, of Tring, and Mr. Bonhote, of Cambridge, who acted most efficiently as secretaries, while Mr. C. E. Fagan, of the British Museum, looked after the finances as treasurer. These gentlemen were assisted in their duties by Dr. Godman, Mr. Meade-Waldo, Mr. Ogilvie-Grant, Dr. Penrose, the Hon. Walter Rothschild, Dr. Sclater, and Mr. Witherby, who were all members of the organising committee. Many other well known British ornithologists attended the meetings, such as Sir Walter Buller, Dr. Butler, Mr. Dresser, Colonel Godwin-Austen, Mr. Harting, Mr. Pearson, Mr. Pycraft, Mr. Howard Saunders, and Mr. D. Seth-Smith. The French ornithologists were represented by Dr. Oustalet and Dr. Bureau, the German by Graf Hans v. Berlepsch, Dr. Blasius, and Prof. Reichenow, the Dutch by Dr. Büttikofer and Baron Snouckaert van Schauburg, the Austrian by Dr. Lorenz and Dr. Reiser, and the Italian by Dr. Giglioli and Count Arrigoni degli Oddi. From America came Mr. F. M. Chapman and Dr. Stejneger, from Switzerland Prof. Fatio and Dr. Studer, from Russia Dr. Bianchi and Baron Loudon, from Bulgaria Dr. Paul Leverkühn, from Canada Mr. Fleming, from Hungary Dr. Herman, and from Belgium Dr. A. Dubois, all names well known in ornithological science.

The first general meeting of the congress took place in the morning of June 13, when Dr. Oustalet, the last president, gave up the chair to Dr. Bowdler Sharpe, the new president, who delivered a most instructive address on the origin and progress of the great national bird-collection in the British Museum, which is under his charge. The meeting was then divided into five sections:—(1) systematic ornithology and distribution; (2) migration; (3) biology and oology; (4) economic ornithology; and (5) aviculture, which sat at stated periods throughout the week. To the first section, which was presided over by Dr. P. L. Sclater, F.R.S., about fourteen communications were made, among which were papers by Graf v. Berlepsch on new neotropical birds, by Mr. Pycraft on the importance of the study of nestling birds, which was illustrated by various pregnant instances of the secrets they have already revealed and are likely to betray in the future, and by Padre Schmitz on the birds of Madeira. In this section also, Dr. Reiser, of Serajevo, exhibited the series of North-Brazilian birds which had been obtained during Dr. Steindachner's recent expedition to the Rio St. Francisco, and Mr. Walter Rothschild showed his unique copy of "Les Voyages de Sieur B.," with the map attached, which contains much information on the now extinct birds of the Mascarene Islands.

In the second section, which met on Tuesday and Saturday, with Dr. Herman, of Buda-Pesth, in the chair, Mr. J. H. Fleming gave particulars of an unusual migratory visit of Brunnich's murre to the

interior of Canada, and Dr. Helm brought forward some new observations on the migration of the starling in Germany.

The third section, for biology, nidification and oology, was presided over by Dr. Victor Fatio, of Geneva, and received communications from the Rev. C. R. Jourdain on erythrism in eggs, and from Dr. R. Blasius on the bird-life of the Pyrenees. In this section also, Mr. Frank M. Chapman, of New York, delighted his audience by his vivid description of the breeding-places of the scarlet flamingo and brown pelican in the Bahamas, which he had lately visited, and by his excellent photographic illustrations of these birds and their nests.

Mr. H. E. Dresser took the presidential chair in the fourth section, which was devoted to economic ornithology and the protection of birds, and was well attended. Papers were read here by Dr. Herman on his recent observations on the constituents of the food of birds, by Sir John Cockburn on the legislation that had taken place in Australia for the preservation of bird-life, and by Mr. T. Digby-Pigott on the present state of the laws on the same subject in Great Britain and Ireland, which seem to require careful revision. Mr. Frank E. Lemon, secretary of the Royal Society for the Protection of Birds, also lectured on the same subject.

In section five (aviculture) the communications were not so numerous, but Mr. D. Seth-Smith, the editor of the *Avicultural Journal*, did not omit to urge the importance of his special branch of ornithology as an aid to scientific study, which, indeed, is now generally admitted.

Besides the sections, general meetings were held on the Wednesday and Friday, at which various ornithological topics of general interest were discussed. Papers were read by Dr. Paul Leverkühn, of Sophia, on the breeding-places of the vultures and eagles in the Balkans, by Dr. Herman on the state of ornithology in Hungary and on the theory of the migration of birds and its origin, and by Mr. J. L. Bonhote on the hybridisation of ducks; while Mr. W. S. Bruce gave an interesting account of the ornithological results of the Scottish Antarctic Expedition which are now being worked out. Besides these papers, Dr. Edward Wilson gave an excellent lecture on the birds obtained and observed in the Antarctic seas and lands during the recent National Antarctic Expedition, and showed off the manners and customs of the penguins in a long series of photographs.

Thursday, June 15, was entirely devoted to a visit to the great zoological museum at Tring, of which the birds (under the curatorship of Dr. Hartert) form one of the most prominent features. It is needless to say that the ornithologists were most hospitably received and entertained by Mr. Walter Rothschild, who further delighted the visitors by a lecture on birds extinct or likely soon to become so, one of his pet subjects of study. This lecture was illustrated by the exhibition of a splendid series of specimens of the birds in question, for which the Tring Museum is celebrated, and by numerous drawings collected from every quarter whence information on this subject could be obtained.

At the final meeting, held on Saturday, June 17, it was agreed that the next assemblage of the International Ornithological Congress should take place in 1910 in Germany, with Dr. Reichenow, of Berlin, as president, and Dr. R. Blasius and Graf Hans von Berlepsch as vice-presidents. It was hoped that the meeting would be held at Berlin, but the president and vice-presidents were authorised to select any other city in Germany as the place of assemblage in case they should find it more expedient to do so. It was also agreed, on the motion of Mr. Walter Rothschild, to send telegrams to the Governments of Tasmania and New Zealand requesting them to interfere with the destruction of the penguins in the Antarctic islands now carried on in order to obtain the small quantity of oil which is contained in the bodies of these unfortunate birds.

THE THAMES FLOW AND BRITISH PRESSURE AND RAINFALL CHANGES.

DURING the years 1903 and 1904 there appeared two reports dealing with the flow of the Thames in relation to the rainfall of the river's basin, the first being published by the London County Council and the second by the Thames Conservators. The material dealt with extended over the period 1883 to 1903, and the very close association between rainfall and flow was clearly brought out.

In a recent communication to the Royal Society by Sir Norman Lockyer and the writer, an attempt has been made to discuss data from the year 1860 up to the present time, involving not only statistics of rain-

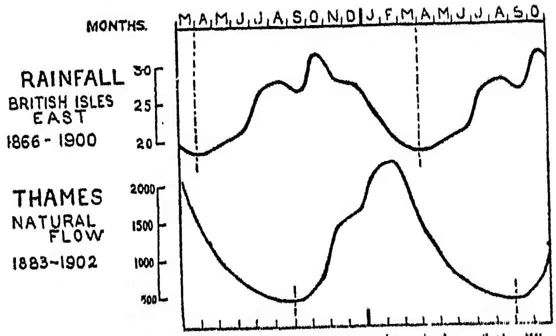

FIG. 1.—The curve representing the mean annual variation of the Thames flow lags five months behind that of the mean annual rainfall of the British Isles.

fall over a wider area than that dealt with in the above mentioned inquiries, but changes of barometric pressure in Great Britain and certain distant areas.

In consequence of the fact that the British annual variation of rainfall is at a minimum in about April and a maximum in about October, the rainfall observations have been grouped into twelve months extending from April to the following March, both months inclusive. The annual variation of the river flow (see Fig. 1) for similar reasons necessitated a different grouping of the twelve months; in this case the year was taken to cover the period September to the following August, both months inclusive. The flow of the river will thus be seen to lag five months behind the rainfall.

In the following curves here reproduced the rainfall for each group of twelve months (April to March) is compared directly with the river flow for the twelve months commencing in September of the same year.

Re-computing the rainfall and river statistics, published in the above mentioned reports, according to these new divisions of the year, the changes from year to year can be seen in Fig. 2 (curves iii. and iv. continuous lines). To investigate variation in the river flow previous to 1883, an application to the Thames Conservators resulted in securing original data which have enabled the curve to be traced back to the year 1860 (Fig. 2, curve iii., dotted portion). As a check on the whole of this curve another series of gauge readings was similarly treated, and these are shown in curve ii. The synchronous variations in

the two curves thus indicate that either curve may be taken to represent the flow changes.

In the above mentioned reports the curve representing the rainfall of the river basin from 1883 (curve iv.) was deduced from the statistics of twelve stations covering a comparatively small area. It happens, however, that these rainfall variations in this valley are not restricted to this region alone, but are similar to those which occur over a very large area in the British Isles. By employing the Meteorological Office records, and computing them according to the present adopted system of grouping of months, curves can be obtained which commence in the year 1866. Investigation has shown that this type of variation is nearly common to England S., Midland Counties, and even the combination of Scotland E., England N.E. and E., and the Midlands, as can be gathered from the curves in Fig. 2 (curves v., vi., vii.).

The other districts in the British Isles (with the exception of Scotland N., which is different from all other districts in these isles) are of a type similar to each other, but present variations which, although not widely different from the eastern and other districts, are sufficiently unlike them to be classified apart.

The rainfall of the British Isles is produced mainly by the passage of areas of low pressure travelling over the country in a north-easterly or easterly direction. It should therefore be expected that on the average the greater the rainfall the more numerous the cyclones, and consequently the lower the mean value of pressure. In the United Kingdom, therefore, the rainfall variations from year to year should correspond very closely with the *inverted* pressure changes. That this is so can be seen by comparing the *inverted* Oxford pressure curve in Fig. 2 (curve viii.) with the rainfall curves underneath. Instead of Oxford, any other town in the United Kingdom, such as Armagh, might have been taken (curve ix.), for the pressure changes are so remarkably similar over a very wide area.

It will thus be seen that the pressure, rainfall, and river flow are all intimately related, and any method of forecasting pressure would make it possible to determine beforehand the rainfall. Since the Thames flow has a lag of five months on both rainfall and pressure, a means is possibly available of stating the "expectancy" of excessive or deficient amount of water in the river.

It may here be pointed out that it does not seem necessary to collect and discuss the data over the whole of this region before any deduction *for practical purposes* can be made regarding the flow of the Thames. The barometric and rainfall observations made at the Radcliffe Observatory, Oxford, exhibit variations from 1860 up to the present time so very similar to those of the Thames flow that all three curves are very nearly interchangeable.

So striking is the agreement that they are here reproduced (Fig. 3).

The question now arises, can British pressure be forecasted?

It has been previously pointed out in this Journal (vol. lxx. p. 177, June, 1904) that there exists a world-wide barometric see-saw between two nearly antipodal parts of the earth, the one region about India and its neighbourhood behaving in an *inverse* way to that of South America and the southern parts of the United States. In some regions, and the British Isles was one of them, the pressure variation curves were found to be a distinct mixture of both the Indian and South American types, and it was difficult to classify them.

To illustrate this, the accompanying figure is given

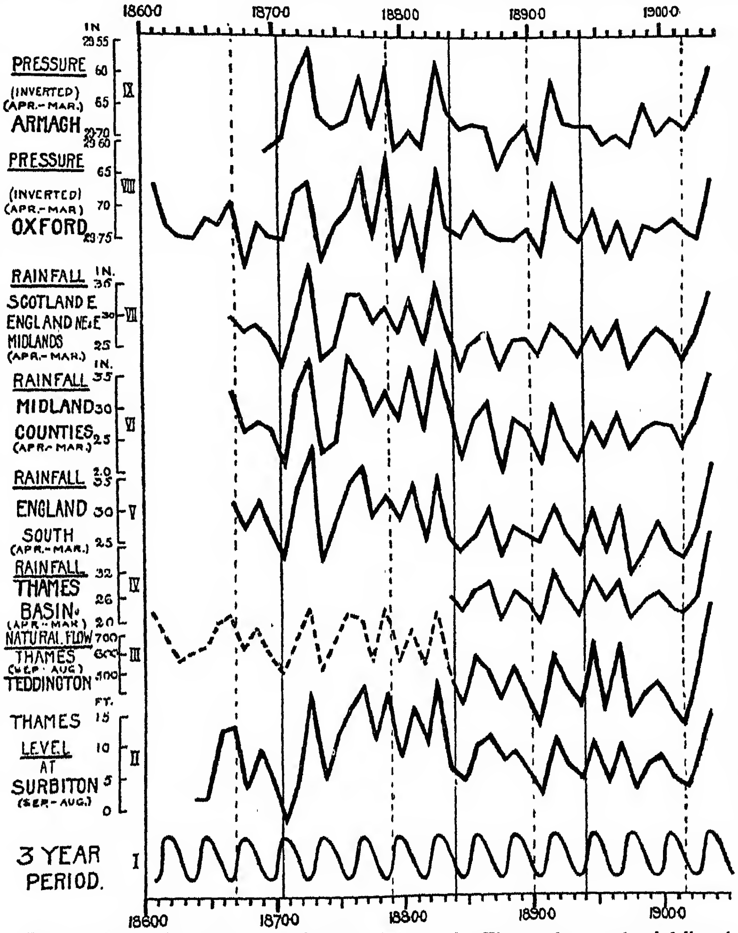

FIG. 2.—Curves illustrating the similarity between the Thames flow, and rainfall and pressure (curves inverted) in the British Isles. [The continuous and dotted vertical lines represent the epochs of sun-spot maxima and minima respectively.]

(Fig. 4). The upper curve represents an hypothetical curve with a period of 3·8 years, and beneath it the South American (Cordoba) pressure curve. At the very bottom is given the *inverse* of this hypothetical curve, and above this the Indian (Bombay) curve. Between the Bombay and the Cordoba curves is given that of Oxford. It will be noted that the Cordoba curve disagrees with its hypothetical curve in the years 1892 and 1900 to 1903, while the Bombay curve shows anomalies in 1892 and 1901 to 1903.

If, now, the Oxford pressure be compared with those of Cordoba and India, and a list made showing the years in which high pressure at Oxford coincides with years of high pressure at Cordoba or India, or low pressure at Oxford with low pressure at Cordoba

or India, the following table is the result (omitting average conditions):—

Agreement between Oxford and		Years of simultaneous excess: High pressure		Low pressure
Cordoba	...	1874	...	—
,,	...	1875	..	—
,,	...	—	...	1877
India	...	—	...	1878
,,	...	1880	...	—
,,	...	—	...	1882
,,	...	1884	...	—
,,	...	—	...	1886
Cordoba	...	1893	...	—
,,	...	—	...	1895
India	...	1896	...	—
,,	...	1899	...	—

It will be seen that there is a very even balancing between Cordoba and India. A most interesting point is that the Oxford curve seems to favour for series of years the two main pressure types alternately. From 1900 the type of variation seems somewhat indefinite.

This table seems to suggest that during some years the British area is enveloped in the pressure system that extends over the large region in which India is about the centre, while for another series it is dominated by the antipodal pressure system of which South America is the middle portion.

It is possible that it is this alternate reversion from one type to the other that prevents the 3·8-year change of the Indian and Cordoba curves from occurring in the British curves, and substitutes for it an apparent shorter period of about three years, which is very noticeable for some series of years in the British curves (Fig. 2, curve i.).

It will thus be seen that it is difficult at present to forecast British pressure correctly, but further research will very probably render it possible when more is known about the mechanism of the atmosphere.

In conclusion, it is interesting to note that in addition to this short period variation the curves (Fig. 2) indicate one of longer duration. An examination of these statistics, when the curves are smoothed by taking three-year means to eliminate the short period changes, shows that when the river flow was greatest, *i.e.* between about the years 1873–1883, the rainfall was highest and the pressure lowest, which is exactly what was to be expected from the relationship between pressure, rainfall, and river flow in these islands. Another point here indicated is that this long period change is real, and that there is a tendency now for the low river levels, deficiency of rainfall, and excess pressure of the last decade or more to be replaced by a greater mean flow of the river, increase in the rainfall, and a diminution in the barometric pressure.

WILLIAM J. S. LOCKYER.

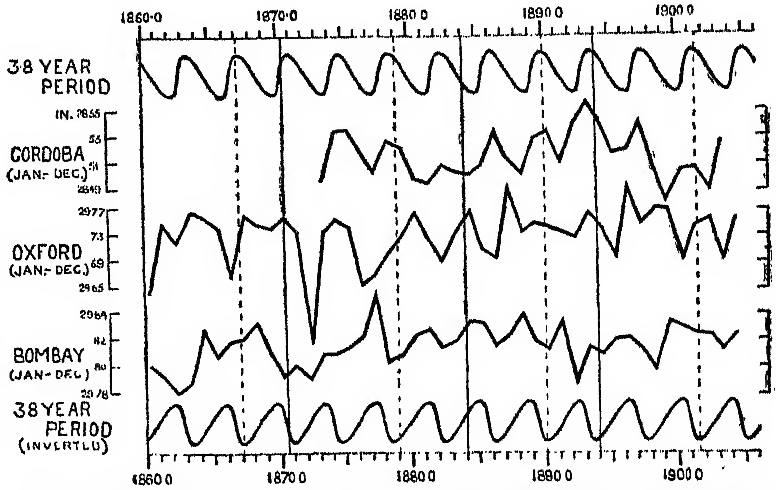

FIG. 4.—Curve to illustrate the relation between the British (Oxford) pressure change and those of India (Bombay) and S. America (Cordoba).

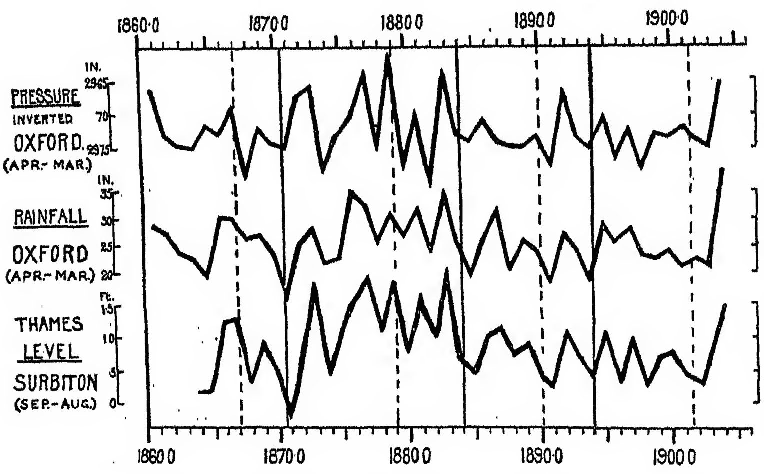

FIG. 3.—Curves to show the similarity between the flow of the Thames and the rainfall and pressure (inverted) changes at one station, namely, Oxford.

NOTES.

A ROYAL garden party was held on Wednesday, June 14, and was attended by about six thousand guests. At the end of the official record of notable people present, supplied to the *Times* by the "Court Newsman," we read:—"Invitations were issued to their Excellencies the Foreign Ambassadors and Ministers, with the *personnel* of their Embassies and Legations, the members of the Government, the Households of the King and Queen and of the Royal Family, and to many peers, members of Parliament, naval and military officers, clergy, and representatives of the musical, dramatic, and literary professions, many of whom with their wives and daughters were present at the party." We believe His Majesty the King is interested in the scientific as in the other activities of his subjects; but if so, it is clear that he is very badly served by the Lord Chamberlain's office, which is responsible for the issue of the invitations. Apparently, this department of the State has not yet realised that science is the only true basis of a nation's welfare and progress, and that scientific men exist in Britain. A few of the most distinguished Fellows of the Royal Society would represent the best interests of the nation even more effectively than actors and musicians.

THE Royal Society's annual conversazione, to which ladies are invited, will take place on Friday, June 23.

PROF. E. RAY LANKESTER, F.R.S., has been elected president of the British Association for the meeting to be held at York next year.

THE Stephen Ralli memorial—a laboratory for clinical and pathological research—will be opened at the Sussex County Hospital, Brighton, on Thursday next, June 29.

AT the Borough Polytechnic Institute on Wednesday next, June 28, marble busts of Joseph Lancaster and Michael Faraday (the work of Mr. H. C. Fehr), presented to the institute by Mr. Passmore Edwards, will be formally unveiled by Prof. S. P. Thompson, F.R.S. Mr. Edric Bayley, chairman of the governors, will preside.

THE annual conversazione of the Royal Geographical Society will be held at the Natural History Museum, South Kensington, on Tuesday next, June 27.

AT the meeting of the Royal Geographical Society to be held in the evening of June 26, a paper will be read by Dr. Charcot on the French Antarctic Expedition. Dr. Charcot has just been created a Chevalier of the Legion of Honour.

WE learn from the *Times* that the Government of India has ordered the introduction of a standard time, with effect from July 1, on the railways (other than small local lines, where the change might be inconvenient) and in all telegraph offices in the country, and also in Burma. Hitherto Madras time has been adopted by most of the Indian railways. The standard now to be introduced is nine minutes in advance of the "railway time," as it is called in all parts of India, and is thus 5½ hours in advance of Greenwich, being the local time of longitude 82° 30′. The standard for Burma is to be exactly an hour earlier, viz. 6½ hours in advance of Greenwich and five minutes earlier than Rangoon local time. In inland places it has been found convenient generally to follow railway time; but the great seaports of Calcutta, Bombay, and Karachi have followed the local time of their respective longitudes. The Government of India does not prescribe the new standard for these and other places following local time, but if a general desire to adopt the new standard is evinced, the Government will be prepared to support the change and to cooperate in bringing it about. In all probability, therefore, there will, ere long, be a uniform time throughout India exactly 5½ hours in advance of Greenwich, while that of Burma will be 6½ hours in advance.

THE death of Mr. James Mansergh, F.R.S., on June 15, at seventy-one years of age, deprives applied science of an acknowledged authority upon water supply and sewage disposal. Mr. Mansergh had unique experience and knowledge of these subjects, and was associated for many years with almost every important construction connected with them in this country. The extensive schemes which he initiated and directed for the improvement of water supply and drainage will long remain as monuments to his memory. He was the designer of the waterworks and sewerage of Lancaster (where he was born in April, 1834), Lincoln, Stockton, Middlesbrough, Rotherham, Southport, Burton-on-Trent, Melbourne (Australia), Birmingham, and many other large towns. These designs include some of the largest schemes of water supply and drainage ever carried out, such, for instance, as the sewerage scheme for the metropolitan district of Melbourne, embracing an area of 133 square miles, and the supply of water to Birmingham from a source in Radnorshire seventy-three miles away. This scheme utilises water from the rivers Elan and Claerwen, and natural reservoirs have been formed for the water by constructing immense dams below the point where the two rivers meet. Mr. Mansergh was the author of about 150 reports upon schemes of water supply, sewerage, and sewage disposal for many large towns. He was also the author of "Lectures on Water Supply: Prospecting for Water, Prospecting and Boring," delivered at the School of Military Engineering, Chatham, "The Water Supply of Towns," and other works. While president of the Institution of Civil Engineers in 1900-1, the Engineering Standards Committee was formed, and Mr. Mansergh was elected chairman. At the time of his death, as chairman of the main committee, he had more than thirty committees working on standardisation in different branches of engineering. Mr. Mansergh was a member of the Royal Commission on Metropolitan Water Supply, and he was on the council of the Institution of Mechanical Engineers. He was elected a Fellow of the Royal Society in 1901 for his eminent work as a hydraulic engineer.

IN the *Irish Naturalist* for June Dr. R. F. Scharff records the capture of two female bottle-nosed dolphins in Dublin Bay in April last. The only other record of the occurrence of *Tursiops tursio* in Irish waters dates from 1829. Dr. Scharff figures one of the Dublin specimens.

WE have received a copy of the March issue of the Bulletin of the Cracow Academy, to which Mr. V. Kulczyński contributes the continuation of an article on certain spiders, treating in this instance of *Araneus cucurbitinus* and its allies. In other articles Mr. T. Browicz discusses the secreting function of the nucleus in the cells of the liver, while Mr. K. Wójcik describes the infra-Oligocene strata of Riszkania, near Uzsok, with lists of the fossils.

A NOTICEABLE feature in the report of the Zoological Society of Philadelphia for the past year is the attention paid to the causes of the deaths which take place in the menagerie. In 140 instances a pathological examination was instituted, mostly with definite results in determining the cause of decease. The results are tabulated, and show that tuberculosis is by far the most fatal ailment, next to which comes inflammation of the stomach and intestines, followed, with a considerable diminution in the numbers, by nephritis, necrosis of the liver, and non-tubercular pneumonia.

IN the April issue of the *Emu* the editors continue the excellent practice of giving coloured illustrations of some of the more remarkable Australian birds, the plate, which is drawn by Mr. H. Grönvold, depicting in this instance representatives of Xerophila, Mirafra, and Amytis. In the case of *Xerophila castaneiventris,* one cannot help wondering what is the purpose of the pair of yellow eye-like spots at the root of the beak. Among the articles is an interesting account, with photographs, by Mr. A. J. Campbell, one of the editors, of that remarkable bird the kagu of New Caledonia, in the course of which attention is directed to the danger of extermination now threatening that species. Thirty years ago it had already disappeared from the more settled parts of Caledonia, and the writer urges that steps should be taken, while there is yet time, to preserve such an interesting bird (the sole representative of its genus) from extermination.

THE problems of "vitalismus" are discussed by Mr. K. C. Schneider, of Vienna, in *Biologisches Centralblatt* of June 1 at considerable length; while in another article Dr. H. Schmidt, of Jena, enters on the consideration of the fundamental law of biological development. In a

third communication Dr. R. Rössle insists on the importance of immunity-reactions (that is to say, serum reactions and blood-immunity) in determining the systematic affinities of the higher animals, pointing out that by this method the intimate affinities respectively existing between fowls and pigeons, horse and ass, fox and dog, and sheep and goats, have already been established. The translation of an article by Prof. Marcus Hartog, published in the *Proceedings of the Royal Society,* constitutes the next most important part of the contents of this issue.

THE most important articles in *Indian Public Health* for May (vol. i., No. 10) deal with the milk question in India and the Calcutta milk supply.

SOME interesting observations on the influence of the root nodules upon the composition of soy beans and cowpeas have been made by Messrs. C. D. Smith and F. W. Robison (Bulletin No. 224 Michigan State Agricultural College Experiment Station). The conclusion is arrived at, after two years' work, that while on fairly fertile soils the root nodules may not notably increase the yield, they do cause an important and pronounced increase in the relative and absolute amount of nitrogen in the plants.

BULLETIN No. 23, by Dr. Herzog, of the Bureau of Government Laboratories, Manila, is devoted to a consideration of plague, and a description of the pathological findings in twenty cases which occurred in Manila. A new species of rat flea (*Pulex philippensis*) is described. Bulletin No. 24, by Dr. Wherry, gives a report of two cases of human glanders which occurred in Manila, and some notes on the bacteriology and morphology of the *Bacillus mallei.*

IN the *Bull. Internat. de l'Acad. des Sciences de Cracovie* (No. 1, January) M. Panek contributes a chemical and bacteriological study of the Polish "barszcz," a product of the fermentation of red beetroot. It is brought about by a micro-organism, named by the author *Bacterium betae viscosum,* which causes a fermentation of the cane-sugar with the production of viscous substances and mannite. M. Tochtermann describes the action of thionyl chloride on thiobenzamide, M. Niemczycki discusses syntheses effected by means of zinc chloride, and Madame Krahelska the merogonic development of the egg of *Echinus microtuberculatus.*

THERE has been a considerable amount of uncertainty with regard to the blackwood of southern India, whether it was possible to distinguish two species. Mr. T. E. Bourdillon, writing in the *Indian Forester* (March), is able to show that *Dalbergia sissoides* and *Dalbergia latifolia* should be regarded as distinct species. The natives recognise dark blackwood, species latifolia, and pale blackwood, species sissoides, and although there are several points of distinction, the wood forms the best means of identification.

To the Cowthorpe oak which grows near Wetherby, in Yorkshire, and was illustrated in NATURE of May 11 (p. 44), is generally assigned the honour of being the largest tree in the British Isles. The claim is based upon the girth and spread of the tree, as it is doubtful whether it ever attained a great height. The *Yorkshire Herald,* May 29, provides an illustration, reproduced from a painting, which is believed to be an accurate representation of the tree as it appeared sixty years ago, and extracts are given from a pamphlet issued with the picture. There is no doubt that this oak passed through its seedling stage several centuries ago; Dr. Jessop, in 1829, suggested an age exceeding 1500 years, but this is mere conjecture, as the tree has been hollow for at least two centuries.

THE eighteenth and latest volume of the *Transactions of the Royal Scottish Arboricultural Society* contains the accounts of the society's meetings during 1904, the jubilee year. The president, Mr. W. S. Fotheringam, in reviewing the progress of the society, announced that the list of members had reached a thousand. The yearly excursion which was held in France provided an opportunity of visiting some of the magnificent State forests. At Champenoux and Haye the forests are principally oak, but beech and hornbeam are also grown, since they provide useful cover. Previously the system adopted was coppice-with-standards, but in both cases this is being converted into high forest. A very fine forest of silver-fir worked with a rotation of 144 years was inspected at Celles, in the Vosges.

PROF. E. WIEDEMANN, of Erlangen, sends us a short statement of observations described in his work on electric discharges (*Wied. Ann.*, xx., p. 793, 1883) relating to the effects referred to by the Rev. F. J. Jervis-Smith in our correspondence columns on May 4 (p. 7). He agrees with Mr. Jervis-Smith as to the action of ozone, and advises persons who work for a long while with influence machines not to have these machines situated in the working room. "Ozone belongs to the poisonous gases and is the more dangerous, since the injurious effects are not manifest at the time; on the contrary, breathing the gas produces at first a feeling of exhilaration, but afterwards it has a depressing effect on the nervous system. Binz has shown that it may cause sleep. I may add to what I have mentioned that during my observations I have suffered somewhat severely from nervous disturbance (hyperasthesia of the feet) due to breathing ozone. These lasted for one or two years. Moreover, I always experience discomfort after performing experiments in my lectures on Tesla discharges."

SINCE March, 1904, several meteorological stations have been established by the Japanese Government along the coast of Korea. In April of that year the Japanese meteorological observatory in Chemulpo commenced to record observations. Mr. H. Mukasa, writing from Chemulpo, informs us that a new building for the observatory was completed lately on the top of the highest hill in Chemulpo (lat. 37° 29′ N., long. 126° 37′ E.), seventy metres above mean sea-level, where observations have been taken since January 1 last. At the invitation of Dr. Y. Wada, the director, the important residents of Seoul and Chemulpo visited the observatory on March 25 last. Various pieces of apparatus relating to meteorology, as well as the horizontal seismograph devised by Prof. F. Omori, were exhibited. Among the visitors were the Japanese, French, and British Ministers, and several Korean dignitaries. The exhibition succeeded in arousing the interest of the visitors in meteorology, and made a deep impression on the Korean guests.

WE have received a copy of the first report of the Transvaal Meteorological Department, containing observations for one year ending June 30, 1904, with an appendix giving monthly and seasonal rainfall records for a number of years, from observations taken before the establishment of the meteorological department. This was only constituted in April, 1904, consequently the records are very incomplete, so far as official stations are concerned. In some cases a complete year's observations are pub-

lished, thanks to the courtesy of volunteer observers. The department has, however, lost no time in obtaining properly verified instruments, but the difficulties may be gathered from the fact that out of two consignments of grass minimum thermometers only one instrument survived the transport. The heights of the stations are not yet accurately known; many of them have an altitude of 5000 feet to 6000 feet.

THE thirteenth yearly report of the Sonnblick Society for the year 1904 contains an interesting account of some of the results obtained at the highest mountain meteorological stations of Europe, with photographic illustrations; the arduous work done in the interest of meteorological and physical science at some of these inhospitable localities has from time to time been referred to in our columns. In the present report A. Edler von Obermayr discusses the frequency of sunshine at the summit of the Sonnblick (3106 metres) with that at other mountain stations. The tables exhibit some peculiarities:—on Ben Nevis the greatest frequency occurs in June, on the Obir and Säntis in July and August, but on the Sonnblick the greatest frequency occurs exclusively in the winter months, from November to February. A useful index is given in a separate paper of the various items and unusual occurrences contained in the Sonnblick reports for the twelve years 1892–1903.

IN his earliest researches on the properties of gaseous fluorine, M. Henri Moissan showed that it reacted vigorously with nitric acid, fluorine and the vapour of the acid producing a violent explosion. In the current number of the *Comptes rendus* MM. Moissan and Lebeau give an account of a systematic research on the reactions between fluorine and the compounds of nitrogen and oxygen. Nitrogen peroxide and nitrous oxide proved to be perfectly indifferent towards fluorine, but a lively reaction, accompanied by flame, was found to take place between fluorine and nitric oxide. With the nitric oxide in excess, the gaseous products proved to be nitrogen, nitric oxide, and nitrogen peroxide, the fluorine appearing in the form of a solid product of indefinite composition containing platinum (from the tube by which the gas was led in) and nitrous compounds. But with the fluorine in excess, the reaction appeared to be more definite, and a gaseous compound containing fluorine, nitrogen, and oxygen was produced, the substance being solid at the temperature of boiling oxygen. This solid, when allowed to boil off, could be condensed to a colourless liquid at −80° C., and further work is being carried out with the view of establishing its composition and properties.

A SHORT report has been received upon the present state of the work done in connection with the "Technolexicon" of the Society of German Engineers. In the compilation of this universal technical dictionary for translation purposes (in German, French, and English), which was commenced in 1901, about 2000 firms and individual collaborators are assisting at present. Up to now 2,700,000 word-cards have been collected; and this number does not include hundreds of thousands of cards that will result from the working out of the original contributions not yet taken in hand. The editor-in-chief of the "Technolexicon" is Dr. Hubert Jansen, Berlin (NW. 7), Dorotheenstrasse 49, and he will be glad to give any information concerning the work.

A KEY to the first part of "A New Trigonometry for Schools," by Mr. W. G. Borchardt and the Rev. A. D. Perrott, has been published by Messrs. Geo. Bell and Sons.

OUR ASTRONOMICAL COLUMN.

STARS WITH PECULIAR SPECTRA.—Mrs. Fleming has discovered several more new variable stars and other objects having peculiar spectra whilst examining the Henry Draper memorial plates. The designation, position for 1900, magnitude and spectral peculiarities are given for each of these in No. 98 of the Harvard College Observatory Circulars. Several of the objects mentioned have bright lines in their spectra, and one or two call for special remark. For example, a star in Cepheus at R.A. = 0h. 7·6m., dec. = +71° 32′, was found to have a spectrum containing five bright bands at λλ 3869, 4101, 4340, 4688, and 4861. The first of these coincides with the bright band seen in certain gaseous nebulæ, the second, third, and fifth will be recognised as due to hydrogen, whilst the fourth, the brightest of all, corresponds to the characteristic line seen in fifth-type stars. The chief nebula line at λ 5000 was not seen. Prof. Pickering suggests that this object may have arrived at an intermediate stage between a nebula and a fifth-type star.

Another star situated in the position R.A. = 1h. 50·2m., dec. = +62° 49′, in the constellation Cassiopeia, is now classed as a gaseous nebula, its spectrum consisting of the chief nebula line at λ 5000.

A second table in the same Circular describes the spectra of twenty-one known variables, and Prof. Pickering states that in most cases of long-period variables the bright hydrogen lines are not seen during the epochs of minima.

VARIABLE STARS IN THE CLUSTERS MESSIER 3 AND 5.—The hundredth Harvard College Circular contains a discussion by Prof. Bailey of the variable stars discovered in the clusters Messier 3 and Messier 5. These two clusters contain a greater proportion of variable stars than any other hitherto examined. Of every seven stars in the former one is a variable, whilst in Messier 5 the ratio is 1 : 11. Periods have been determined for most of the variable stars, and their similarity is remarkable. Only two stars, Nos. 42 and 50 in Messier 5, having periods of 25·74d. and 105·6d. respectively, appear to depart from the rule, all the other variables in both clusters having periods differing but little from 13h. The average deviation from the mean (13h.) in Messier 3 is 1h. 0m., and in Messier 5 (mean 12h. 45m.) 1h. 13m. All the variables are of nearly the same magnitude, varying from 13·0m. to 16·0m., and there is a slight suggestion that the periods of them undergo a secular variation in length.

SPECTROHELIOGRAPH RESULTS.—In No. 4, vol. xxi., of the *Astrophysical Journal*, Mr. Phillip Fox, of the Yerkes Observatory, discusses the observations made with the Rumford spectroheliograph during 1904. The plates secured with the H_2 radiation, *i.e.* the radiation of the centre of the H calcium line, show a decided increase of activity in the flocculi over that observed during 1903, and are being measured in order to determine the solar rotation period at the height, above the photosphere, of the high-level flocculi.

Many series of plates, on which the individual exposures were made at intervals of a few minutes, the successive settings of the secondary slit being made in ten or twelve steps from λ 3952·4 to λ 3968·6, were secured, and Mr. Fox briefly discusses these in regard to the distinction between faculæ and flocculi in the calcium vapour images. Such a series of photographs, taken on August 25, is reproduced on one of the plates accompanying the paper, and shows that few, if any, flocculi appear in the high levels without their bases appearing, although usually diminished, in the lower levels. Even the bright patches designated "eruptions" by Messrs. Hale and Ellerman can be traced as such as far down as the photograph taken with the secondary slit set at λ 3967. The photographs secured with the hydrogen radiations $H\beta$, $H\gamma$, and $H\epsilon$ generally show flocculi coincident with those seen on the calcium photographs, and in nearly all cases where the eruptions could be traced to the limb associated prominences were discovered above the flocculus.

No prominences of great height or unusual form were photographed on the limb during 1904, but some of the plates show a fair number, and one or two beautiful examples are reproduced on the second plate of the paper.

VISIBILITY OF D_3 AS A DARK LINE IN THE SOLAR SPECTRUM.—At a recent meeting of the Royal Astronomical Society, Prof. A. Fowler stated, in a paper on the spectrum of the great sun-spot of February last, that he had, on February 2, observed the helium line D_3 as a dark and distorted line in the spectrum of the sun in the region about the spot disturbance. This observation was regarded as unusual, but according to a letter written by Mr. A. Buss to the *Observatory* (No. 358) it is not at all an uncommon phenomenon, and can be seen frequently if the solar spectrum be closely watched. In fact, Mr. Buss states that, according to his observations with a curved slit spectroscope, D_3 may be seen as a dark line in every really agitated solar disturbance.

WEST HENDON HOUSE OBSERVATORY.—No. 3 of the Publications of the West Hendon House Observatory (Sunderland) is devoted to the observations of variable stars made by Mr. Backhouse during the years 1866–1904. The observations of each of the forty-nine stars discussed are set out in detail in tables showing the times of observation, the comparison stars, and the magnitudes according to other catalogues. For a number of stars the observed magnitudes are plotted on a series of curves placed at the end of the volume, with a diagram showing the various gradations of colour employed in the descriptions.

NATURE AND MAN.

THE annual Romanes lecture was delivered by Prof. E. Ray Lankester, F.R.S., in the Sheldonian Theatre, Oxford, on June 14, on the subject of "Nature and Man." The complete lecture has been published by the Clarendon Press (London: Henry Frowde), and the following abstract indicates a few of the points considered in it.

Prof. Lankester remarked that the subject of his discourse is one which has largely occupied the attention of biologists during the five-and-forty years in which he has followed the results of scientific discovery. Much misconception prevails as to the signification attached to the word "Nature," but the lecturer used it as indicating the entire cosmos of which this cooling globe with all upon it is a portion. Until the eighteenth century the study of nature—nature-knowledge and nature-control—was the appropriate occupation of the learned men at Oxford, and the present peculiar classical education is a modern innovation.

During the latter half of the nineteenth century, the observations of nature-searchers made it possible to establish the general doctrine of the evolution of the cosmos, with more special detail in regard to the history of the earth and the development of man from a lower animal ancestry. The general process by which the higher and more elaborate forms of life, and eventually man himself, have been produced was shown by Darwin to depend upon heredity and variation. By the process of natural selection, those organisms survive which are most fitted to the special conditions under which they live. Man eventually emerged from the terrestrial animal population strictly controlled and moulded by natural selection. The leading feature in the development and separation of man from other animals is the relatively large size of his brain, which has five or six times the bulk (in proportion to his size and weight) of that of any other surviving Simian. The development of the mental qualities has given rise to attributes which are peculiar to man, and justify the view that man forms a new departure in the gradual unfolding of nature's predestined scheme.

"Civilised man has proceeded so far in his interference with extra-human nature, has produced for himself and the living organisms associated with him such a special state of things by his rebellion against natural selection and his defiance of nature's pre-human dispositions, that he must either go on and acquire firmer control of the conditions or perish miserably by the vengeance certain to fall on the half-hearted meddler in great affairs." It is practically certain that all epidemic disease could be abolished within a period so short as fifty years if the State cared to take the matter in hand and employ the means at the command of science. If more men were encouraged to study and experiment on this matter, there would soon be an end of all infectious disease.

By the exercise of his will, man has done much to control the order of nature, and it is urgent for him to apply his whole strength and capacity in gaining further control. Little, however, is being done in this direction, but when a knowledge of the situation reaches the masses of the people, "the democracy will demand that those who expend the resources of the community, and as Government officials undertake the organisation of the defence and other great public services for the common good, shall put into practice the power of nature-control which has been gained by mankind, and shall exert every sinew to obtain more. To effect this, the democracy will demand that those who carry on public affairs shall not be persons solely acquainted with the elegant fancies and stories of past ages, but shall be trained in the acquisition of natural knowledge and keenly active in the skilful application of nature-control to the development of the well-being of the community."

The concluding subject of the lecture was the influence exerted by the University of Oxford upon the welfare of the State and of the human community in general. Oxford by its present action in regard to the choice of subjects of study "is exercising an injurious influence upon the education of the country, and especially upon the education of those who will hereafter occupy positions of influence, and will largely determine both the action of the State and the education and opinions of those who will in turn succeed them." Is it desirable to continue to make the study of two dead languages the main, if not the exclusive, matter to which the minds of the youth of the well-to-do class are directed by our schools and universities? In view of modern needs it would be more sensible to make the chief subject of education for everybody "a knowledge of nature as set forth in the sciences, which are spoken of as physics, chemistry, geology, and biology." The ablest youths of the country should be encouraged to proceed to the extreme limit of present knowledge of one of these branches of science so that they might become makers of new knowledge, and the possible discoverers of enduring improvements in our control of nature. The great prizes of life ought to be given to the young man who pursues nature-knowledge successfully rather than to him who takes up less important subjects. In other words, it is desirable that our scheme of education should centre round a knowledge of nature and not continue to be mainly classical and historical.

Though men of science would make natural knowledge the core of education, they would consider it incomplete if a serviceable knowledge of foreign languages, and a real acquaintance with the beauties of English and other literature, were not added. "The studies of the past carried on at Oxford have been charming and full of beauty, whilst England has lain, and lies, in mortal peril for lack of knowledge of nature."

The suggestion "that Oxford should resign herself to the overwhelming predominance given to the study of ancient elegance and historic wisdom within her walls" is an insult to her and an impossibility. Only a few decades have passed since Oxford sent out Robert Boyle and Christopher Wren. Moreover, Oxford exerts an immense influence on the schools, and for this reason men of science cannot be content with the maintenance by the university of the compulsory study of Greek and Latin, and the neglect to make the study of nature an integral and predominant part of every man's education. For "the knowledge and control of nature is man's destiny and his greatest need."

SCIENCE AND THE STATE.

THE seventh of the series of weekly pamphlets which are appearing under the editorship of Mr. W. T. Stead, with the general title of "Coming Men on Coming Questions," is by Mr. R. B. Haldane, and is entitled "The Executive Brain of the British Empire." Mr. Haldane is an enthusiast for higher education. He is a thorough believer in the policy which has been advocated

consistently by NATURE, that the surest and best way to secure national efficiency is to educate our manufacturers and merchants liberally along scientific lines, and to enlist the cooperation of distinguished men of science in the work of national administration.

In considering the task that lies before a progressive political party, Mr. Haldane has much of interest to the man of science to say about things the party has to accomplish in the process of winning complete public confidence in its capacity to direct national business. He points out that the importance of each Department of State depends mainly on the personality of the Minister who presides over it. But apart from personality there are other forces —such as clear conception and resolute purpose—which profoundly affect administration. To bring into play greater brain power in administration is, Mr. Haldane insists, a task of the first magnitude, and he proceeds to show its importance and how it may be accomplished.

The appointment of the Explosives Committee by Lord Lansdowne in 1900 is the first illustration taken by Mr. Haldane. After the outbreak of the South African war, it came to light that the British military and naval guns were being corroded rapidly by the chemical action at high temperatures of the products of combustion of the nitroglycerin in the cordite. Lord Lansdowne, who summoned outsiders to advise him, was told that an expert committee on the national explosives required the best scientific brains in the country, and, following the earlier example in France, a committee, presided over by Lord Rayleigh and including Sir Andrew Noble and Sir William Crookes, was appointed. The committee has solved the problems presented to it, made further discoveries, and is now a permanent body. But the committee is performing its work under great difficulties, due entirely to our system of administration. As Mr. Haldane says, "the Army gives its rewards to genius on the field, and not to genius in the laboratory." He says later:—"If the British Government is to have adequate command of scientific talent of the highest order, it must make arrangements which will enable it to reward and honour that talent on an adequate scale, without exciting ill-feeling."

There ought, in fact, Mr. Haldane contends, to be an advisory body with a *corps scientifique* attached to it, which should include the exceptional talent which the State stands more and more in need of every day. Not only would such a scientific committee provide a new opening for talent, but, more important, prove a source of new strength to the nation. As a further instance of the good results which promptly follow the application of scientific methods to national problems, Mr. Haldane cites the case of the discovery among miners of the disease ankylostomiasis, after the Home Office had obtained the permission of the Treasury to appoint a committee of investigation, and indicates how great would have been the saving of suffering and money had there been a *corps scientifique* to appeal to as a matter of course.

Referring to the fall in the amount of exports in some branches of industry, Mr. Haldane traces this to the need for more mind in the process of manufacture, that is, for the improvement of higher education in this country, and goes on to remark that comparatively little State aid has been devoted to this important necessity. Exception is taken, too, to the somewhat mechanical methods of distribution of the present grant from the Treasury to university colleges, and it is urged that in this direction also the executive brain ought to be strengthened.

The Centralstelle of Germany, the function of which is to put at the disposal of inquirers, in the solution of problems arising in manufacture, the best scientific knowledge available which cannot otherwise be obtained by the private manufacturer, is an example of Germany's appreciation of men of science. Not only are such central research institutions established in Germany, but also in the United States and in France. The same principle has been conceded among us, for the State gives a small grant —just about a tenth of what the Germans give to their corresponding institution—to the National Physical Laboratory, an invaluable institution which is at present being starved. Well may Mr. Haldane say that "it is time for the State to take the lead in this direction also, if we are to hold our own in the international competition which is more and more coming to depend on the application of science to industry."

The essay as a whole is a powerful plea for the introduction of the methods of science into every department of national life, and should convince every reader that disregard of scientific method and procedure is of necessity accompanied by a want of national efficiency and wellbeing.

CORAL ANATOMY AND DEVELOPMENT.[1]

IN writing this account of his observations and researches on Siderastræa, Dr. Duerden has added an important contribution to his already extensive publications on the anatomy and development of the Madreporaria. Siderastræa is a common West Indian coral forming colonies of 10 cm. to 60 cm. in diameter, which encrust stones and sometimes the shells of hermit crabs on the coral flats. It appears to be exceedingly hardy, as it will suffer exposure to the hot sun at low tide and partial burying in the mud without injury, and it is often found living under conditions on the reef which very few corals of other species could withstand. This hardiness renders it an admirable type for thorough investigation, as it enables it to live and grow and reproduce itself freely in the unfavourable conditions of an aquarium in the tropics.

Siderastræa, although a colonial coral having a general superficial resemblance to the Astræidæ, or star corals, is allied to the Fungidæ, or mushroom corals. The tissues of the expanded zooids are so transparent that the white

FIG. 1.—Three larvæ of Siderastræa settling down upon a stone, in close proximity, by their narrow aboral poles.

skeletal structures can be seen through them. Each zooid has, in the adult state, two rows of capitate tentacles, and several of the members of the inner row are bifurcate. This remarkable and, among corals, unique condition of the tentacle is brought about by the growth of a common peduncle for a pair of neighbouring tentacles of the entocœlic series which are primarily distinct.

In all the zooids that were examined anatomically only ova were found; Dr. Duerden, however, gives reasons for believing that the coral is not strictly diœcious, but protogynous, a point of some interest when compared with the case of *Flabellum rubrum*, which Mr. Stanley Gardiner has shown to be protandrous.

The early stages of the development of the coral take place within the cavity of the parent zooid, and the ciliated top-shaped larvæ are discharged with four pairs of mesenteries already developed. The larvæ can be kept alive in the aquaria for several weeks, but unless they settle down within the first two or three days from liberation it seems impossible for them to fix themselves, and they ultimately perish. In general the larvæ fix themselves at the same time and in groups. So close do they cluster together that they are often in touch with one another,

[1] "The Coral *Siderastraea radians* and its Post-larval Development." By Dr. J. E. Duerden. Pp. 130+plates. (Washington: Carnegie Institution, December, 1904.)

and by mutual pressure produce a distortion of the normally circular base. There can be no doubt that in this coral, as in others investigated by Dr. Duerden, these clusters of larvæ become organically connected, and form aggregated colonies.

In dealing with the later stages of the development, the author discusses many questions of great interest to those who have made a special study of the anatomy of corals. We may refer especially to the light thrown upon the vexed question of "theca" and "epitheca," to the demonstration that the primary ectosepta do not become entosepta as they were supposed to do in some other corals, and to the valuable suggestion as to the scientific method of writing the septal formulæ of corals. These and other matters, which are fully discussed, render the memoir of greater value than a mere record of facts and observations of the natural history of a single species of coral would be. There is a great deal to be said in favour of the old type system, the system of presenting to the reader a plain, unvarnished tale of the natural history of a species and leaving him to draw his own conclusions; but the dangers of the system may be clearly recognised

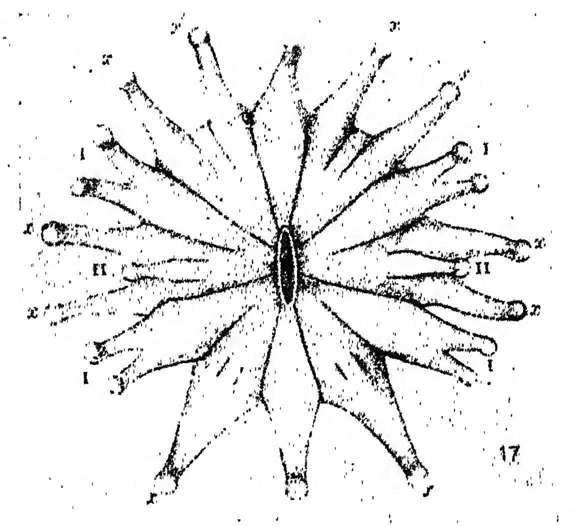

FIG. 2.—The disc of a young Zooid of Siderastræa with expanded tentacles showing (I.I.) the four bifurcate tentacles of the inner row.

in this memoir. The coral under review is a common, and many might think a common-place, coral, and if the author had thought fit to limit himself to a description of facts only, it would probably have been chosen as a type of its order by writers of the conventional text-book. Fortunately, however, we are warned on almost every page that Siderastræa is not a type, but in many respects an exceptional and rather archaic form.

In conclusion, a word of praise must be said for the manner in which the memoir is presented to the public. Like the other scientific treatises that have been recently published by the Carnegie Institution at Washington, the paper, printing, and illustrations are all of first-rate quality.

S. J. H.

GAS CALORIMETRY.

IN the recent report of the Departmental Committee appointed to consider the question of the control of the gas supply of the metropolis, a proposal was made that the calorific power of the gas should be regularly determined, thus recognising the growing importance of the heating value of gas as distinguished from its illuminating power. The use of gaseous fuel both for heating and power purposes having led to a demand for exact gas calorimetry, several types of calorimeter have come into use. In those of the Junker type, the gas is burned at a measured rate, and the products of combustion are cooled down by a stream of water also flowing at a known rate, the ingoing and outgoing temperatures of which can be accurately measured. In spite of the difficulties of securing accurate measurements of the rate of flow of gas and water, on account of the speed with which consecutive determinations can be carried out instruments of this type are mostly used by gas engineers. Their chief defect is want of portability, and as an alternative a sample of the gas is frequently analysed, and the calorific value deduced from the results of the analysis. Apart from the difficulty of exactly determining the constituents of such a complicated mixture as coal gas, this method implies that the exact calorific value of each substance present is accurately known, and this, unfortunately, is far from being the case.

Most of the data regarding heats of combustion in actual use are derived either from the experiments of Berthelot and his pupils with the calorimetric bomb, or from the experiments of Julius Thomsen, and in the case of gaseous substances the differences between these two experimenters may amount to as much as 2 per cent. In the current number of the *Zeitschrift für physikalische Chemie* Julius Thomsen has a critical paper on the causes of these differences, and comes to the conclusion that for gases the explosion with compressed oxygen in a bomb gives quite untrustworthy results. His chief argument is based on the comparison of the values obtained for the heats of combustion of homologous series of hydrocarbons and their halogen derivatives, and it is shown that whereas the method of combustion at ordinary atmospheric pressure gives remarkably constant differences between the consecutive members of such a series, the results obtained by means of the calorimetric bomb lead to differences between consecutive members which are quite irregular. It follows that the values obtained for heats of formation, which lie at the basis of all theoretical speculations in this field, are still more irregular in the case of figures obtained with the bomb, since they are based on the differences between the heats of combustion. The weak point in most physical work on gases is usually on the chemical side, and on account of the extreme practical and theoretical importance of the subject and the great advances made in the last ten years in the methods of preparation of pure gases, there is still room for a re-determination of these constants. In this connection it may be pointed out that the ultimate mode of calibration of gas calorimeters of the Junker type is the combustion of a known quantity of a pure gas the heat of combustion of which is taken as known.

G. N. H.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The following is the text of the speech delivered by Prof. Love in presenting Prof. E. Ray Lankester for the degree of D.Sc. *honoris causa* on June 13:—

Salutat Academia nostra Edwinum Ray Lankester, alumnum suum. Hic ille est, cuius magna apud nos est memoria Anatomiæ Comparativæ cathedram olim tenentis, quod et discipulis ardorem suum miro modo inspirare potuit, et specimina in usum Musæi nostri diligentissime congesta ita novis rationibus collocavit ut Historiæ Naturalis principia luce clariore illustraret: qui hanc Academiam ut suos mores emendaret toties hortatus est, quæ ad inauditam perfectionem iamdudum pervenisset si monitori amicissimo in Actis Diurnis contionanti obtemperare voluisset. Hic est cuius ex repertis laudis aliquid ad suam Almam Matrem redundavit, cum inter insignissimos doctores qui hodie de animalium figuris disputant fere princeps sit et in omnibus virorum doctorum societatibus summo in honore habeatur.

Nihil profecto quod ad Anatomiam Comparativam pertinet non in huius viri scientiam cadere videtur. Neque enim huic satis erat edendi curam suscipere cum Acta illa, quæ summæ auctoritatis in hoc genere apud nos sunt, labore per quinque et triginta annos iam continuato, tum luculentissimorum librorum seriem, e quibus plures iam typis impressi in manibus omnium habentur, quod onus

pergrave videri plerisque potuit: sed de omnigenum animalium figuris et mutationibus, sive in ipsa mundi iuventa sive hodie exstantium, commentarios fere innumerabiles ipse conscripsit. Nullum est animalium genus de quo aliquid non scripserit, neque quicquam scripsit nisi præclare. In hoc viro admiramur cum summi artificis patientiam nullam rem tenuiorem esse docentis quam ut scientia dignum sit, tum doctrinam latissimam et subtilissimam nova inventa cum prioribus colligantis et suo quidque loco reponentis. Sed ulterius etiam progressus est. Quid enim? Incrementum fit scientiæ non solum ex indefessa diligentia et doctrina coacervata summorum veri indagatorum: quin ipsa diligentia et doctrina parum fertilis est nisi conclusiones ita verbis et tabulis expressæ sint ut in memoria nostra hæreant et novissimum quodque repertum suo loco residere patiantur. Veluti hic noster, qui iuvenis adhuc rationes a Ioanne Müllero et Huxleio excogitatas, quo melius omnia ad Historiam Naturalem pertinentia subtilissime litteris mandarent, se optime callere ostenderat, postea novos modos invenit, nova nomina commentatus est, veteres etiam rationes correxit et excoluit: quæ omnia iam adeo omnibus comprobata sunt ut nemo inquirat a quo fonte emanarint. Quod si ex hac præclara supellectili unam quasi margaritam potissimum sumere fas sit, eos commentarios singulari laude ornaverim, quibus Limulum illum aquatilem scorpiones et araneas terrestres inter se similes esse ostendit. Nihil profecto in hoc genere perfectius, nihil quod posterorum imitatione sit dignius.

Following the announcement in the *University Gazette*, the age limits in the examination to be held on August 29 for the selection of probationers for the Indian Forestry Service were stated in our note on June 8 (p. 139) to be from eighteen to twenty years on January 1, 1905; Prof. Schlich writes to point out that the correct age limits are from eighteen to twenty-one years on that date.

Dr. W. T. Brooks (Christ Church) has been appointed Litchfield clinical lecturer in medicine for two years from June.

A statute has been passed in Convocation establishing a diploma in anthropology, and providing a committee to organise the course of study in that subject, and to make regulations for the diploma examination. The committee will consist of seventeen members, including the professors of anthropology, comparative anatomy, moral and metaphysical philosophy, comparative philology, the reader in mental philosophy, the keeper of the Ashmolean Museum, and the curator of the Pitt Rivers Museum. Candidates who are not already members of the university will be admitted under the same conditions as candidates for the degrees of B.Litt. and B.Sc.

Magdalen College has announced a fellowship in chemistry, election to which will be made next October term after an examination. Further details will be published shortly.

CAMBRIDGE.—The following are the speeches delivered by the Public Orator, Dr. Sandys, on June 14, in presenting the two recipients of the degree of Doctor in Science *honoris causa*:—

CAPTAIN ROBERT FALCON SCOTT, R.N., C.V.O.

Poli australis e regione salvum sospitemque nobis redditum laetamur virum intrepidum, cui disciplina et gloria navalis ab avo velut hereditate obvenerat. Abhinc annos quinque navis magister designatus est, rerum naturae miraculis prope polum australem explorandis destinatae. Illic, primum terrae Victoriae montes asperos conspicatus, deinde ex transverso oppositum glaciei velut murum immensum diu praetervectus, tandem nivis aeternae regionem quandam excelsam detexit, detectam Regis Edwardi nomine nuncupavit. Quid commemorem navem illam prope montem Erebum, prope ipsa Volcani spiracula, glaciei solidae in mediis molibus per biennium compressam? Quid geographiae, geologiae, meteorologiae, biologiae denique in studiis, scientiarum fines, talium virorum auxilio, feliciter propagatos? Quid itinera longa glaciei perpetuae inter pericula tolerata? Tot virorum fortium de duce intrepido illud primum dixerim:—omnium mortalium nemo umquam ad ipsum polum australem propius penetravit. Deinde, "numquam" sociis suis "plus laboris imposuit quam sibi sumpsit; ipse cum fortis, tum etiam felix."

SIR FRANCIS YOUNGHUSBAND, K.C.I.E.

Hodie corona nostra suprema viro destinata est, qui matris suae fratrem, exploratorem indefessum, olim aemulatus, omnium mortalium solus, oceani Pacifici a litore trans Asiae mediae recessus intimos septem milia passuum milies emensus, montium formidolosorum per ambages prope inextricabiles, Indiae demum ad castra prima pervenit. Idem nuper, Britanniae legatus, cum copiis nostris fortissimis, Indiae per Alpes silvasque, post moras infinitas fortiter et prudenter devictas, per apertam portam, Tibetorum ad loca praecelsa ultra lacum illum caeruleum progressus, tandem, inter nemora late virentia, arcis summae tecta aurea conspicatus, religionis antiquissimae sedem sacram, tot laborum, tot itinerum metam ultimam, intravit. In legatione vero illa obeunda, viri huiusce potissimum auspicio, terrae spatia immensa accuratissime explorata sunt; fluminum ingentium cursus patefacti; saeculorum denique priorum monumenta plurima aut intacta relicta aut diligenter conservata. Iuvat autem recordari regionem illam remotissimam cum exercitu nostro legatum nostrum ita peragrasse, ut nullum crudelitatis, nullum inhumanitatis vestigium reliquerit, sed benevolentiae mutuae, etiam foedere ipso potioris, fundamentum iecerit.

Mr. E. T. Whittaker, of Trinity College, has been appointed a university lecturer in mathematics.

The Home Secretary has approved the university for the purposes of the Coal Mines Regulation Act (1887) Amendment Act, 1903, in respect of its diploma in mining engineering.

The Harkness scholarship in geology and palæontology has been awarded to Mr. F. A. Potts, of Trinity Hall, and the Wiltshire prize for geology and mineralogy to Mr. A. McDonald, of Emmanuel College.

The treasurer to the Sedgwick memorial fund, which was inaugurated in the Senate House on March 25, 1873, has issued a final balance sheet. The original subscription list amounted to 11,157*l*. 1*s*. 6*d*., and this sum increased by investment to 27,453*l*. 2*s*. 4*d*. A thousand guineas were spent on the bronze statue of Sedgwick, and 26,125*l*. on the Sedgwick Museum; the balance was mainly expended on printing, but a small sum left over has been paid to the financial board.

DR. JAMES GOW will distribute the certificates and prizes at King's College, London, on Wednesday, July 5. The museums and laboratories of the college will be open to visitors upon this occasion.

DR. A. B. W. KENNEDY, F.R.S., will deliver the foundation oration of the Union Society of University College, London, on June 29; his subject will be "The Academic Side of Technical Training."

AMONG the honorary degrees accepted by the Senate of the University of Dublin on June 17 was the degree of Sc.D. to be conferred on Prof. E. A. Schäfer, F.R.S., and on Prof. Sydney Young, F.R.S.

MR. G. F. CARSON, formerly on the staff of the University College, Sheffield, has been appointed head of the department of mathematics in Battersea Polytechnic, and Miss Lilian J. Clarke has been appointed lecturer in botany.

AT the entrance examination for the day courses in engineering to be held next September, the governing body of the Northampton Institute, Clerkenwell, has decided to offer three scholarships for open competition. These scholarships will give exemption from fees, amounting to 52*l*., during the whole of the four years' course in mechanical or electrical engineering.

DURING December next, in the department of physics of the Columbia University, New York City, a course of fifteen lectures will be delivered by Prof. V. F. Bjerknes, professor of mechanics and mathematical physics in the University of Stockholm. The subject will be "Fields of Force," including the discussion of hydrodynamic analogies of the electrostatic and electromagnetic fields. A similar

course will be delivered in March and April, 1906, by Prof. H. A. Lorentz, professor of physics in the University of Leyden.

Under the title "The Education of the Examiner," Dr. Charles E. Fawsitt publishes, in the *Proceedings of the Royal Philosophical Society of Glasgow*, an interesting note on the statistics of examination marks as revealed by graphic methods. Most examiners who have had to draw curves showing the distribution of marks in any examination know the difficulty of obtaining an even uniform curve rising continuously to a maximum and then descending continuously. However carefully the scale of marking is adjusted, the curve has an unpleasant habit of showing two maxima, usually of unequal height, instead of the one maximum of the generally recognised standard curve. Dr. Fawsitt, as the result of observations on class examinations conducted at Edinburgh, brings forward the welcome suggestion that this irregularity is not the fault of the examiner, but is due to the fact that the candidates naturally divide themselves into two sets, namely, workers and non-workers, and that while the students in either set vary in every conceivable way in respect of *ability*, a marked line of division is drawn with regard to work. The superposition of two error curves, in accordance with this theory, gives results closely agreeing with those of common experience.

SOCIETIES AND ACADEMIES.

London.

Royal Society, March 16.—"On the Dimorphism of the English Species of Nummulites, and the Size of the Megalosphere in relation to that of the Microspheric and Megalospheric Tests in this Genus." By J. J. **Lister**, F.R.S.

The results obtained in this investigation are summarised as follows:—

(1) Both microspheric and megalospheric forms of *N. variolarius* and *N. Orbignyi* var. *elegans* are present in the Eocene beds of the Isle of Wight and Hampshire, as the author believes they will be found to be present elsewhere, except when the materials of a bed have been re-arranged under the influence of currents.

(2) In these species and in *N. laevigatus* and *N. gizehensis* the size of the microsphere is nearly constant—the diameters in the specimens measured being between 15 μ and 20 μ.

(3) In the nine species and one variety of Nummulites which the author has examined, the size of the megalosphere is approximately proportional to the volume of the contents of the microspheric form.

By this result additional proof is given of de la Harpe's conclusion, founded on the mode of occurrence in the beds, and on structural features of the tests of the two forms, that these are in each case truly members of "a pair," or, as we now say, are related as alternating or recurring forms in the life-history of a species.

By (2) and (3) the two modes of reproduction come into marked contrast, the asexually produced megalospheres being proportional in size to the protoplasmic volume of the parent, while the microsphere, probably arising as a zygote, is uniformly small throughout.

(4) In several of the species examined, as the microspheric member of the cycle preponderates in the life-history, the megalospheric (or gamete-producing) member decreases, not only in proportion to the size of the microspheric form, but in proportion to the megalospheric members of other species in which the two forms attain approximately equal sizes.

April 6.—"Ovulation and Degeneration of Ova in the Rabbit." By Walter **Heape**. Communicated by Adam Sedgwick, F.R.S.

This paper is an abstract of several years' experimental work. The growth of the graafian vesicle and ovum, and the modification of the adjoining ovarian tissue, are referred to. The maturation of the ovum takes place in the ovary. It is dependent upon coition, and follows a cessation of the supply of nutriment to the ovum. Ovulation occurs ten hours after copulation, and does not occur if coition is prevented.

The cause of the rupture of the graafian vesicle is probably due to the stimulation of ovarian contractile tissue, to effect which, in the domestic rabbit, the excitement of sexual contact appears to be necessary.

The prevention of coition results in the degeneration of ripe follicles, and the production of false corpora lutea. Such degenerate follicles do not rupture, and the ovum contained therein is not discharged. The structure and fate of the true and false corpora lutea are briefly described.

The persistent prevention of breeding causes degeneration of young as well as ripe follicles on a large scale, and results in more or less obstinate sterility.

Degeneration of young follicles occurs normally. While this may be due to want of nutriment, caused by competition of neighbouring follicles, it may also be due to incapacity to assimilate the nutriment which is supplied.

In this latter case, failure is due to a peculiarity in the constitution of the ovum, constituting it a "sport." As there is evidence that the production of variable offspring depends upon the quality or quantity of nutriment supplied to the mother, it is urged that the study of nutrition from this point of view becomes a matter of very great interest and importance to students of heredity.

A brief review of the evidence concerning the forces which influence breeding results in the conclusion that changes are induced in the constitution of the blood by means of a "generative ferment" of extraneous origin; the effect of which upon the generative glands causes their secretion of "gonadin," which exercises a profound effect upon the rest of the generative system.

"On the Nature of the Silver Reaction in Animal and Vegetable Tissues." By Prof. A. B. **Macallum**.

When fresh preparations of animal and vegetable tissues are treated with a solution of nitrate of silver containing free nitric acid and then exposed to light, they become coloured, the colour varying in intensity and tint. The author endeavoured to determine to what the reaction is due, and how far one may go in employing it for microchemical purposes. It was found that of the organic constituents of tissues, the only ones which form compounds with silver "reducible" under the action of light are sulphocyanic acid, creatin, and taurin. As creatin is present only in vertebrate muscle fibre, and not at all in invertebrates, while the other compounds mentioned occur in tissues only in infinitesimal, and, therefore, in negligible, quantities, the silver reaction cannot be attributed to their presence. It was further ascertained that neither phosphates, carbonates, nor sulphates give "reducible" silver compounds in the presence of free nitric acid. There remained, among organic compounds in tissues, only the proteids, and as these have been, and are, generally held to form, with silver salts, compounds which are "reduced" in light, it was necessary to determine whether the coloured compounds so formed are "albuminates" or simply the subchloride of silver. For this purpose proteids were freed from chlorides by repeated precipitation with pure ammonium sulphate, and it was found that egg and serum albumins and globulins, as well as the gelatins, after the eighth precipitation give no colour reaction whatever with nitrate of silver under the influence of light, and that the compounds eliminated by the precipitation, and to which the silver reaction is due, are chlorides. Nucleo-proteids also were found to be reactionless. In the case of vegetable proteids the methods employed were different, but the result was the same. Silver nitrate may, consequently, be used as a microchemical reagent for determining the presence of chlorides in animal and vegetable tissues, and its use for this purpose has already furnished some important results. Amongst these may be mentioned the absolute freedom of the nucleus from chlorides, the absence of the latter from the head of the spermatozoon, and the demonstration that they alone are the cause of the silver reaction in the "cement substance" (of von Recklinghausen) as well as in ordinary cell protoplasm.

May 18.—"Reciprocal Innervation of Antagonistic Muscles." Eighth Note. By Prof. C. S. **Sherrington**, F.R.S.

Exhibition of strychnine converts reflex inhibition of muscles into excitation; so also, more gradually, but just as potently, does *tetanus-toxin*. This conversion sets in before and under smaller doses of strychnine or toxin than are required to produce the convulsive seizures characteristic of strychnine poisoning or general tetanus.

The conversion of inhibitory effect into excitation effect by strychnine is more easily obtained in the case of some nerves than of others.

The conversion of spinal inhibition into excitation by strychnine explains the simultaneous contraction of large inharmonious groups of muscles in strychnine convulsions. It also explains the occurrence, under a given stimulus of reflex contraction, of muscles that previously do not seem, under superficial examination, to be reached by the reaction. These muscles are really included in the reflex effect normally, but the effect on them then being *inhibition*, it passes unnoticed, unless special means are adopted for seeing it. Thus, in the ordinary "flexion reflex," initiated, say, from the right foot, the flexion of the homonymous knee is easily seen to be due to contraction of its flexor muscles, also the concomitant extension of the crossed knee is easily seen to be due to contraction of its extensor muscles. But it requires special preparations to detect that, with the contraction of the right knee-flexors, there goes reflex inhibition of the right extensor, and that, with the contraction of the left knee-extensor, there goes reflex inhibition of the left knee-flexors. This being so, when under strychnine, the reflex is suddenly changed in character, both flexors and extensors being in both legs thrown into contraction together, it appears to an observer, unaware of the previous inhibitions, that, under the strychnine, the reflex action reached muscles which it did not reach before, *e.g.* right knee-extensor and left knee-flexor. Hence arises the hypothesis that the alkaloid breaks down a supposed spinal "resistance," previously intervening between the afferent nerves and various motor spinal cells ordinarily inaccessible to them. Strychnine does lower the threshold stimulus for spinal reflexes at one stage of its action; but the central fact of strychnine effect appears to the author that it destroys spinal taxis for the skeletal musculature by upsetting the fundamental coordination of reciprocal innervation. It upsets reciprocal innervation because it transforms inhibition into excitation.

On the view advanced in these notes previously that the cortex of the brain exercises reciprocal innervation of antagonistic muscles, strychnine and tetanus-toxin should transform the functional topography of the "motor" cortex. This on examination proves to be the case.

Strychnine and tetanus-toxin change cortical flexion of leg and arm into extension. Reflex "opening" of the jaw is in the decerebrate animal converted into reflex closure by tetanus-toxin and by strychnine, the inhibition of the predominantly powerful closing muscles being converted into excitation of them.

Similarly, when the "face-area" of the monkey's cortex is tested by faradisation after exhibition of strychnine or tetanus-toxin, the points of surface that, prior to the drug, yield regularly the free opening of the jaw, yield strong closure of the jaw instead. Closure of the jaw is, comparatively, an infrequent movement to obtain from the cortex of the monkey. On the other hand, *opening* of the jaw is always readily and regularly elicitable from a large field of the "face-area." Under tetanus toxin and strychnine the whole of this area not only ceases to yield opening of the jaws, either maintained or rhythmic, but yields closing of them instead.

The foregoing observations give an insight into the essential nature of the condition brought about by tetanus and by strychnine poisoning. These disorders work havoc with the coordinating mechanisms of the central nervous system, because, in regard to certain great groups of musculature, they change the reciprocal inhibitions, normally assured by the central nervous mechanisms, into excitations. The sufferer is subjected to a disorder of coordination which, though not necessarily of itself accompanied by physical pain, inflicts on the mind, which still remains clear, a torture inexpressibly distressing. Each attempt to execute certain muscular acts of vital importance, such as the taking of food, is defeated because exactly the opposite act to that intended results from the attempt. The endeavour to open the jaw to take food or drink induces closure of the jaw, because the normal inhibition of the stronger set of muscles—the closing muscles—is by the agent converted into excitation of them. Moreover, the various reflex arcs that cause inhibition of these muscles not only cause excitation of them instead, but are, periodically or more or less constantly, in a state of hyper-excitement, and yet attempt on the part of the sufferer to restrain, to inhibit, their reflex reaction, instead of relaxing them, only heightens their excitation further, and thus exacerbates a rigidity or a convulsion already in progress.

"The Structure and Function of Nerve Fibres.—Preliminary Communication." By Prof. J. S. **Macdonald**. Communicated by Prof. C. S. Sherrington, F.R.S.

In contradiction to certain conclusions[1] arrived at by the author as a consequence of his experimental observation of the "injury current" of nerve, it has recently been denied[2] that inorganic salts occur in any appreciable quantity within the internal structure of the nerve-fibre. This conclusion has been formed as the result of observations made with the use of a reagent—cobalt nitrite—which precipitates potassium salts in a manner open to investigation with the microscope. It has been shown that the reagent does not give rise to precipitates at every point in the length of the nerve-fibre, but only at certain points of infrequent occurrence. The author has checked this statement, also using microscopical methods, and confirms it. He draws, however, an entirely different conclusion from these observations, since he has further observed that these points of infrequent occurrence are points at which the axis-cylinder has been injured in the course of preparation. He concludes that potassium salts are really present in very considerable quantity uniformly distributed along the axis-cylinder, but that they appear in a state of simple solution only at injured points.

The author directs attention to the possible general importance acquired by this observation, when account is taken of the parallelism between injury and "excitation." The sudden appearance of inorganic salts (electrolytes) in a state of simple aqueous solution at an excited point means a transitory increase in local osmotic pressure, new processes of diffusion, and disturbances of electrical potential. In this he sees a sufficient explanation of nerve-conduction. In the case of muscle, also, the influence of similar phenomena is considered, and a possible relation between such an increase in local osmotic pressure and "contraction." He also refers to the possibility of the influence of this factor in the conditions determining the flow of water in plant structures.

June 8.—"The Perturbations of the Bielid Meteors." By Dr. A. M. W. **Downing**, F.R.S.

As the general result of the calculations described in this paper, it appears that the most probable date for the centre of a shower of Bielid meteors this year is November 18, 10h., G.M.T. If there be a shower at that date, it will indicate that the meteor stream is, in this part, of sufficient length to occupy at least thirty-three days (October 16 to November 18) in passing a definite point in its orbit—or that there is another swarm following the main swarm at this interval—and is also of sufficient extent in the direction sun-earth to allow of some of the meteors encountering the earth, although the centre of the stream is more than 1,000,000 miles outside the earth's orbit at the time.

"Chitin in the Carapace of *Pterygotus osiliensis*, from the Silurian of Oesel." By Dr. Otto **Rosenheim**. Communicated by Prof. W. D. Halliburton, F.R.S.

Fragments of the carapace of certain fossil Eurypterids found in Oesel in rocks of Silurian age, from specimens

[1] J. S. Macdonald, "Thompson-Yates Laboratory Reports," vol. iv., part ii., pp. 213–348, 1902; *Proc. Roy. Soc.*, vol. lxvii., pp. 315–324; *ibid.*, pp. 325–328; *Proc. Physiol. Soc.*, December 17, 1904; *ibid.*, March 18, 1905.

[2] A. B. Macallum, *Journal of Physiology*, vol. xxxii. p. 1.

in the British Museum (Natural History), have been examined by the author for chitin.

The conclusion drawn from the experiments is that the general behaviour of the substance towards acids and solvents is such that it is probably chitin, and this is confirmed by the fact that, after such treatment, it yielded, on hydrolysis with concentrated hydrochloric acid, a strongly reducing substance which is presumably glucosamine.

"On the Magnetic Qualities of some Alloys not Containing Iron." By Prof. J. A. **Fleming**, F.R.S., and R. A. **Hadfield**.

For the purposes of exact magnetic measurements two homogeneous rings of regular form of alloys not containing iron were made at the Hadfield Steel Works, Sheffield, and sent to the Pender Electric Laboratory of University College, London. These two rings were respectively numbered No. 1871 and No. 1888/7. The ring No. 1871 had the following composition:—manganese, 22·42 per cent.; copper, 60·49 per cent.; aluminium, 11·65 per cent. There is a certain amount of intermingled slag, probably 2 per cent. or 3 per cent., mostly consisting of MnO and SiO_2 and slight traces of other metals. Analysis showed that there was present also:—carbon, 1·5 per cent.; silicon, 0·37 per cent.; and iron, 0·21 per cent. Hence it may be said that nothing but a trace of iron occurs in this sample of alloy. The other ring, No. 1888/7, had an approximate composition:—manganese, 18 per cent.; copper, 68 per cent.; aluminium, 10 per. cent.; lead, 4 per cent. These alloys unfortunately have poor mechanical properties and are brittle and cannot be forged. Rings were cast from the material and turned in the lathe to the desired form.

From the observations the following conclusions are drawn:—

(1) The alloy No. 1871, composed of copper, aluminium, and manganese in the proportion mentioned above, exhibits magnetic properties which are identical with those of a feebly ferro-magnetic material. (2) The magnetisation (or B, H) curve is of the same general form as that of a ferro-magnetic metal such as cast iron, and indicates that with a sufficient force, a state of magnetic saturation would most probably be attained. (3) The alloy exhibits the phenomenon of magnetic hysteresis. It requires work to reverse the magnetisation of the material and to carry it through a magnetic cycle. (4) The material has a maximum permeability of 28 to 30, which is not greatly inferior to that of the values reached for cobalt or a low grade of cast iron for small magnetic forces, and occupies a position intermediate between the permeability of the ferro-magnetic and the merely para-magnetic bodies, such as liquid oxygen and ferric chloride. (5) The material exhibits, therefore, the phenomenon of magnetic retentivity and coercivity. It is not merely magnetic, but can be permanently magnetised.

The authors are led by these results to conclude that the magnetic properties of this alloy must be based on a certain similarity of molecular structure with the familiar ferro-magnetic metals.

Experiments on the magnetic qualities of the alloy No. 1888/7 give results similar to those of the alloy No. 1871. For both alloys No. 1871 and No. 1888/7 the hysteretic exponents are not very different, being respectively 2·238 and 2·288, whereas the hysteretic constants are very different, being respectively 0·0005495 and 0·000776. It is clear, therefore, that both these alloys, although magnetic, have far greater hysteresis than pure iron, nickel, or cobalt for corresponding cycles of magnetisation.

"Note Supplementary to a Paper 'On the Radio-active Minerals.'" By the Hon. R. J. **Strutt**, F.R.S.

In a paper read before the society on February 28, the author directed attention to the fact that all thorium minerals, so far as could be ascertained, appeared to contain uranium and radium. Since then he has examined a number of additional minerals, in order to test the induction further. The result has been quite confirmatory of the original conclusion. The author, in this further investigation, contented himself with determining the thorium and radium, for it may now be considered proved that radium is a product of uranium, and it is much easier to establish the presence of radium by its emanation than to detect uranium by chemical analysis. The experimental methods explained in the former paper were employed. The results are as follows:—

Mineral	Locality	Thorium oxide, per cent.	Radium, millionths of 1 per cent.
Thorite ...	Ceylon	61·0	1·00
,, ...	Brevig, Sweden ...	53·9	0·81

1 This consisted of pure grains of monazite, picked out from the commercial sand.

Mathematical Society, June 8.—Prof. A. R. Forsyth, president, and temporarily Prof. W. Burnside, vice-president, in the chair.—On the conditions of reducibility of any group of linear substitutions, and On criteria for the finiteness of the order of a group of linear substitutions: Prof. W. **Burnside**. In the first of these papers it is proved that a group of linear substitutions on a finite number of symbols is reducible if, and not unless, one or more linear equations holds between the coefficients of every substitution of the group. In the second paper it is shown that in order that a group of linear substitutions may be of finite order it is necessary that both the real part and the imaginary part of every coefficient should lie between two fixed assignable numbers, and this condition is sufficient.—On a class of many-valued functions defined by a definite integral: G. H. **Hardy**. The integral

$$\int_0^\infty \frac{e^{-u^\lambda}\, u^{a-1}}{u+x}\, du$$

is a many-valued function of x having no singularities save $x=0$, and the behaviour of the function depends on the character of a and λ as rational, algebraic or transcendental numbers. In a number of cases the function can be represented in the neighbourhood of the singular point by a convergent combination of two divergent power series.—Informal communications were made as follows:—The first principles of Cauchy's theory of functions: G. H. **Hardy**.—On differential equations whose integrals are expressible by partial quadratures: Prof. A. R. **Forsyth**.

Royal Astronomical Society, June 9.—Mr. W. H. Maw, president, in the chair.—The discordant values of the principal elliptic coefficients in the moon's longitude: P. H. **Cowell**.—Determination of heat radiation from the moon: the **Earl of Rosse**. The author had found that the lunar heat varied with the phase, that it was negligible at new moon, and attained its maximum at full moon. He considered it a surface heat, not regularly *reflected*, but absorbed and re-emitted. Suggestions were made for future observations during lunar eclipses. Prof. Turner stated that the maximum at full moon might indicate that some of the heat was reflected.—The diurnal variations of nadir and level of the Greenwich transit circle: **Astronomer Royal**. The variation of the level has a period of twenty-four hours, with a maximum about 6 a.m.

and a minimum about 6 p.m. The variations of nadir are much smaller, and do not show any conclusive result except a discordance near 6 p.m.—On the determination of stellar proper motions without reference to meridian places: A. R. **Hinks.**—The meteors from Biela's comet: W. F. **Denning** and Dr. **Downing.**—General scheme for determinations of stellar parallax from photographs taken at the Cambridge Observatory: A. R. **Hinks** and Dr. H. N. **Russell.** A brief account was also given of results already obtained for the parallax of Lalande 21185 and γ Virginis.

Zoological Society, June 6.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—Specimen of a new bushbuck, which it is proposed to call *Tragelaphus haywoodi*, sp. n.: O. **Thomas.** Mr. Thomas also exhibited some mammals and birds from Japan obtained by a collector sent out by the society's president, the Duke of Bedford, K.G., who proposed to further zoological science by having systematic collections made in that part of the world. Of the present series Mr. Thomas directed attention to a fine marten, different from the true *Mustela melampus*, and which he proposed to call *Mustela melampus bedfordi*, subsp. n.—On the intestinal tract of mammals: Dr. P. C. **Mitchell.** In the course of the last eight years, the author had taken every possible opportunity of studying the alimentary tract of mammals from specimens that had died in the society's gardens, and had obtained additional material elsewhere, with the result that his investigations covered more than two hundred individuals, and included the greater number of the mammalian orders. —The natural history of western Uganda, deduced from observations and collections made by the author while acting as British Boundary Commissioner on the Uganda frontiers: Lieut.-Colonel C. **Delmé-Radcliffe.**—Distribution of Mexican Amphibia and Reptilia: Dr. H. **Gadow.** After a critical revision of the species recorded from Mexico, the author stated that he grouped them according to the prevailing physical features of the country. It was found that Mexico had received its present fauna from both the northern and the southern continents. The northern immigrants had spread over high tablelands and mountains, whilst not a few species had descended into the hot lowlands, even into Central America and still further south. On the other hand, the southerners were divided by the plateau into an Atlantic and a Pacific mass, each having had time to modify many of its members according to the very different physical features. Scarcely any of these southerners had ascended the plateau, but they were not averse to ascending high outlying mountains. A comparative list of species confined to high altitudes was given, and the conclusion arrived at, with the help of geological data and the fauna of the Antilles, was that the exchange between the north and south took place during the Miocene epoch, at which period alone the Antilles were connected with Central America.—New species of reptiles discovered in Mexico by Dr. H. Gadow: G. A. **Boulenger.**—Batrachians and reptiles collected in South Africa by Mr. C. H. B. Grant and presented to the British Museum by Mr. C. D. Rudd: G. A. **Boulenger.**—Notes on the anatomy of the yellow-throated lizard, *Gerrhosaurus flavigularis*: F. E. **Beddard.**—Notes on the cerebellum in the exanthematic monitor, *Varanus exanthematicus*, and on the cerebral hemispheres in the Taraguira lizard, *Tropidurus hispidus*: F. E. **Beddard.**—The fœtus and placenta of the spiny mouse, *Acomys cahirinus*: R. **Assheton.** —Some new Coleoptera from South Africa: Rev. H. S. **Gorham.** The beetles referred to were of the families Malacodermata, Cleridæ, and Erotylidæ, and had been collected by Dr. H. Brauns, of Willowmore, in Cape Colony, either at Willowmore or at Delagoa Bay in 1900 or 1901, and indicated that the fauna of South Africa was rich in species of the two first families, and more so than had been supposed in members of the latter family. One new genus was described.—Remarks on the supposed clavicle of the sauropodous dinosaur Diplodocus: Baron Francis **Nopcsa.**

EDINBURGH.

Royal Society, June 5.—Prof. Geikie in the chair.—The distribution of the nerve cells in the intermedio-lateral tract of the dorso-lumbar region of the human spinal cord: Dr. A. **Bruce.** The region was found to extend from the end of the upper third of the eighth cervical to the lower extremity of the second or, perhaps, the upper part of the third lumbar segment, and to occur, not as a continuous tract, but as clusters or groups of cells, separated in some of the upper and lower segments by distinct intervals in which there were no cells, but in the greater part of the dorsal region by incomplete intervals in which there were present a small number of cells. The clusters appeared to be arranged in a manner characteristic more or less of each segment, attaining their maximum number in the third dorsal. The cells lay in the white matter behind the lateral portion of the anterior cornua in the eighth cervical and first dorsal segments; below that point they occupied the apex of the lateral horn, and from the lower part of the second dorsal region they occupied also the grey matter subjacent to the formatio reticularis, and occasionally extending into the formatio reticularis itself. The clusters of cells in this, the reticular group, were frequently continuous with those at the apex of the horn, and belonged undoubtedly to the same system. It was found that the symmetry between the two sides of the cord was not quite complete.—The Tardigrada of the Scottish lochs: J. **Murray.** Twenty-one species were identified, of which six were considered new. It has been usual to distinguish species of Echiniscus by the number and arrangement of the spines and other processes, but in some of the species it was found that spines continue to increase in size at the moult, and that new ones may appear. Also one or two species lay eggs when hardly larger than larvæ, and at successive moults thereafter lay more and larger eggs. In the study of the order there is, in fact, great need for careful tracing of life-histories.—Report on the Medusæ found in the Firth of Clyde (1901–2), and notes on the pelagic fauna: E. T. **Browne.** The report deals with thirty species of Hydromedusæ and five species of Scyphomedusæ, most of which had not previously been found in the Clyde. The fauna is distinctly littoral. Important information as to the seasonal changes in the fauna was obtained. Medusæ are very scarce in winter, and begin to appear about the middle of March. Most of the forms appear during summer, and begin to die off in September and October. The notes on the pelagic fauna contain an account of a number of miscellaneous animals found in the tow-net at different times of year.—Report on the free-swimming Crustacea found in the Firth of Clyde (1901–2): Dr. T. **Scott.** The summer months were the best and richest for plankton in the Clyde, a characteristic feature of the summer being the vast quantities of diatoms. During the winter months the plankton consists almost entirely of five species of copepods.—On a new method of preparing esters: Dr. W. W. **Taylor.** The water formed by the interaction of the acid and alcohol was removed by the addition of benzene, and distillation of the ternary mixture of alcohol, benzene, and water.—Vanishing aggregates of determinant minors: Prof. W. H. **Metzler.**

PARIS.

Academy of Sciences, June 13.—M. Troost in the chair. —The action of fluorine on the oxygen compounds of nitrogen: Henri **Moissan** and Paul **Lebeau** (see p. 183).—The moving shadows of the total eclipse of the sun of May 12, 1706: G. **Rayet.** Reference to some remarks of De Joly concerning the phenomena of moving shadows observed by him during the total eclipse of the sun, May, 1706.—On a solution of Monge's problem relating to the equation $f(dx_1, dx_2, \ldots dx_n)=0$ with variable coefficients: M. **Bottasso.**—The measurement of the capacity of long submarine cables: M. **Devaux-Charbonnel.** The principle of the method consists of charging the cable and a condenser of known capacity placed in cascade, the capacity of the cable being deduced from the charge taken up by the condenser. The method has several advantages over those in current use, and has been applied with success to the cable recently laid between Brest and Dakar.—Thermoelectric power and the Thomson effect: M. **Ponsot.**—Pyrrhotine, ferromagnetic in the magnetic plane and paramagnetic perpendicularly to that plane: Pierre **Weiss.** The atomic susceptibility of iron in pyrrhotine, measured perpendicularly to the magnetic plane, is very near the atomic susceptibility of iron in paramagnetic bodies.—On the true atomic weight of

nitrogen: G. D. **Hinrichs.** The author gives his reasons for supposing that the atomic weights of the elements can be more accurately determined by calculation than by experiment.—On a mode of formation of acetol by the direct oxidation of acetone: M. **Pastureau.** By the oxidation of acetone in acid solution by hydrogen peroxide, the author shows that in addition to the peroxide already described by Baeyer and Villiger, acetol and pyruvic acid are always formed, the yield of the latter amounting to 75 per cent. of the weight of acetone taken. The application of the reaction to higher ketones would appear to show that in addition to the ketone peroxide, the keto-alcohols and ketonic acids are always formed.—The action of sodium on the esters of the fatty acids: M. **Bouveault** and R. **Locquin.** By the action of sodium on a cooled ethereal solution of ethyl butyrate, the principal product is the keto-alcohol C_3H_7—CO—CH(OH)—C_3H_7, a small quantity of dibutyryl also being obtained.—On some aromatic substitution derivatives of ethylene oxide: MM. **Fourneau** and **Tiffeneau.** The substituted ethylene R—CH=CH_2 is treated with iodine and yellow mercuric oxide, and the iodohydrin thus obtained digested with powdered caustic potash. Details are given of the preparation and properties of phenyl, benzyl, methoxyphenyl, and methylphenyl ethylene oxide.—The action of chloroacetic esters on the halogen magnesium derivatives of aniline: F. **Bodroux.**—On some compounds of azelaic acid: A. **Bouchonnet.** The preparation of the phenyl ester and of thioazelaic acid is described.—On sparteine and its reaction with methyl iodide: Charles **Moureu** and Amand **Valeur.** The authors have isolated from this reaction, besides the iodomethylate already known, an isomer, probably a stereoisomer, distinguished by its higher rotatory power and its solubility in water.—On the pyrolysis of gum lac: A. **Etard** and E. **Wallée.**—On the affinity of artificial colouring matters for conjunctive tissue: M. **Curtis** and P. **Lemoult.** A study of the various stains in use in histological work from the point of view of their permanence.—On the reserve carbohydrates in evergreens: Leclerc **du Sablon.**—On a new banana tree of Madagascar: Pascal **Claverie.** The species described appears to be new, and is named by the author *Musa Perrieri*.—On *Oïdium lactis* and the ripening of cream and cheese: P. **Mazé.** Remarks on a paper on the same subject by M. Arthaud-Berthet.—The ancient coastal lines of the Sahel d'Alger: General **de Lamothe.**—On gladkaïte, a new rock in dunite: L. **Duparc** and F. **Pearce.** Veins of the new mineral are found in the dunite mass on the river Wagran in the N. Ural. It is a silicate of iron, alumina, lime, magnesia, soda, and potash.—On the probable yield of the springs in the basin of the Seine during the second quarter of 1905: F. **Launay** and E. **Maillet.**

NEW SOUTH WALES.

Linnean Society, April 26.—Mr. T. Steel, president, in the chair.—Revisional notes on Australian Carabidæ, part ii., tribe vi., Scaritini: T. G. **Sloane.** Critical observations and tabular lists are offered, and six species are described as new.—The possible relationship between bacteria and the gum of *Hakea saligna*: Dr. R. Greig **Smith.** The conclusions to which this research has led are as follow:—(1) The gum of *Hakea saligna* is neither arabin, metarabin, nor pararabin. The hydrolytic products consist of reducing bodies that yield indefinite osazones, and are probably akin to the furfuroïds of Cross, Bevan, and Smith. It is not pectin, although it approaches this substance in some respects. (2) Of the bacteria occurring in the tissues of the plant, the most probable producer of the gum is one intermediate between *Bact. acaciae* and its variety *Bact. metarabinum*, but as we do not yet know that the host plant can alter a gum once formed by a bacterium, it cannot be said that the gum is produced by this micro-organism.—The origin of natural immunity towards the putrefactive bacteria: Dr. R. Greig **Smith.** The author shows:—(1) That there is a close analogy or identity between the production of bacteriolytic bodies and the digestion of food. (2) That bacteria do traverse the intestinal wall, and that negative experimental results regarding the same are untrustworthy. (3) That natural immunity, especially towards the bacteria that normally inhabit the intestinal tract, is occasioned and maintained by the comparatively few bacteria which, in crossing the intestinal wall and possibly gaining access to the body fluids and organs, stimulate the cells to produce immune bodies. (4) That the agglutination of bacteria may claim a much more active part in the production of immunity than is generally supposed.—The probable bacterial origin of the gum of linseed mucilage: Dr. R. Greig **Smith.** Following is a summary of the research:—(1) The gums of linseed mucilages vary in their chemical reactions, and, therefore, probably vary in their chemical constitution. (2) The products of hydrolysis consist of galactose and reducing substances which yield indefinite osazones that are possibly akin to the furfuroïds of Cross, Bevan, and Smith. (3) The gum bacteria in the tissues of Linum are relatively very numerous, and consist chiefly of races of two species. (4) The chemical reactions of the gums from these are practically identical with the reactions of average linseed gum. (5) The gum of one of the bacteria is hydrolysed to galactose, and of the other to galactose and a reducing substance that yields an indefinite osazone. Both gums contain a large proportion of the furfuroïd substances. (6) The gum formed by bacteria is probably altered by the plant into mucilage and other substances required in the plant economy. (7) A number of so-called species of gum bacteria have probably one common origin; the host plant can alter the nature of the gum product which influences the growth characters.

THE FACE OF THE EARTH.

The Face of the Earth (Das Antlitz der Erde). By Prof. Eduard Suess. Translated by Dr. H. B C. Sollas, under the direction of Prof. W. J. Sollas, F.R.S. Vol. i. Pp. xii+604; illustrated. (Oxford: Clarendon Press, 1904.) Price 25s. net.

ENGLISH-SPEAKING geologists will be grateful to Dr. Hertha Sollas and the Clarendon Press for this excellent translation of the first volume of the work which has probably had the deepest influence on geological thought since the publication of Lyell's "Principles." No higher compliment could be offered to such a book than that, twenty years after its publication, it should be worth while to issue a translation without amendment, comment, or other addition than the author's charming letter of introduction. This fact is all the more striking as this volume is mainly a description of the geology of the mountains of the world, and it describes areas of which comparatively little was known in 1884. As Prof. Suess remarks in his introduction, "the reader will meet here and there in the two first volumes with a description already antiquated." This matters the less since we have already an excellent French edition, which has been brought up to date by abundant references to recent literature, and been illustrated by an additional series of maps. The example of the French translators has not been followed, perhaps from the sentimental feeling that as this work is now one of the recognised classics of geology, it should be rendered into English exactly as it came from the hands of the master. This decision will no doubt increase the value of the Oxford edition to future geologists, though it may detract somewhat from its immediate educational usefulness. The absence of the extra maps is an especial drawback to British students, since many of the place-names used are synonyms or transliterations not usually adopted in British atlases. Anything that lessens the educational value of this edition is regrettable, as Suess's work is such magnificent educational material. Prof. Suess's method is to give the detailed evidence upon which he relies; and his readers have the pleasure of working up to the conclusions by the path the author trod. We see his mental process as well as read his results.

This volume opens with a brief statement of some of the geographical homologies which it is the object of the whole work to explain. Prof. Suess dismisses all geometrical plans of the earth, such as Elie de Beaumont's famous *Pentagonal reseau,* as misleading Wills-o'-the-wisp. He fully realises that the first essential to an explanation of the present distribution of oceans and continents is a competent comparison of the facts. As he says, a detailed comparison of observations is necessary before an attempt be made to formulate laws. Suess declines hints as to probabilities from geodesy, and he distrusts speculation as to the hidden parts of the earth. So he studies, with exquisite care, those deeper parts of the crust which have been brought to the surface in the exposed roots of mountains, or which are opened to view by the work of the miner. The two parts of this volume are devoted to a study of the movements in the crust of the earth, and to a description of the mountain system of the world, excluding Australia and some parts of other continents. Prof. Suess concludes from his synthetic study of this wide range of material that the earth's crust is disturbed by movements of two different kinds; firstly, the folding and crumpling of belts of the earth's crust by lateral pressure; and secondly, the foundering of the crust owing to the withdrawal of underground support, consequent on the radial contraction of the globe. Before Suess's time it was usual to regard the distribution of land and water as determined by the uplift as well as the sinking of wide regions. But according to Suess, regional uplifts have never yet been proved, and, excepting perhaps to some local extent, he regards them as impossible. An actual uplift of the surface of the western coast of South America was said to have resulted from the earthquakes of 1822 and 1835. The uplift of the latter was described by Darwin; but Prof. Suess discusses the evidence and dismisses it as wholly inadequate. Any horizontal uplift being, according to Suess, impossible where horizontal marine beds, beaches, or shore-lines occur above sea level, they must be explained by the lowering of the sea, and not by the uprise of the land. Prof. Suess does not hesitate to believe, on the evidence of the plateaus of the Rocky Mountains, that the sea level once stood 30,000 feet higher than at present. If Prof. Suess were to discuss the possibility of regional uplift at the present time, he would have to deal with much weightier evidence than any which he had against him in the year 1884. For the secular uplift of the lake regions of the United States is better established than any of the supposed earthquake elevations of Chili. Moreover, the doctrine of isostasy gives better reason to believe in its possibility. The pendulum work in the Rocky Mountains has rendered it at least possible, that isostasy may account for the horizontal deposits of the high plateaus, which Prof. Suess has described in one of the most brilliant chapters of this volume.

Regional uplifts, however, being dismissed by Prof. Suess, it follows that the main influence in shaping the continents has been the subsidence of wide tracts of the earth's surface beneath sea level. The great ocean basins, and those of the Mediterranean, the Black Sea, and the Caribbean Sea, represent sunken areas of the earth's crust; and foundering to a less depth has caused the rift valleys of Ethiopia, of the Rhine and of Australia, and the basins of Suabia and Franconia. The cause of such subsidences is deep-seated, whereas the crumpling of the long, narrow belts that form the folded mountain chains is due to comparatively superficial action. The two modes of movement may act in the same area at different times. Thus vertical subsidences may destroy the continuity of a folded mountain chain; thus the present form of the Basin Ranges of Utah and Nevada is due to the breaking up, by Cainozoic subsidences, of a series of ranges formed by earlier, post-Jurassic folds. Similarly the outlines of the continents, even when

dependent upon the course of mountain chains, are embayed where the sea has flowed over foundered blocks. The vertical relief of the continents is determined mainly by subsidences, by the resistance of great blocks of strata which remain as plateaus high above the general level of the country, and by the crumpling of bands into mountain chains. The course of such crumpled bands is very sinuous, because they have to adapt themselves to the passive resistance of stronger blocks of the crust; they curve round the margins of the resistant masses, on to the edges of which they may be overthrust. Suess follows, for example, the course of the great Alpine mountain system from its western end in southern Spain, through the Atlas Mountains of Africa, along the the Apennines through Italy, across central Europe as the Alps and Carpathians, and then through the great curve around western Roumania and Servia into the Balkans. Its continuity eastward has been broken by the recent foundering of the Black Sea; but the Alpine system is continued through the Crimea and the Caucasus, and after another gap, caused by the subsidence that formed the southern basin of the Caspian, it is continued across Asia through the Himalaya and the chains of Burma into the islands of Malaysia. Suess explains the sinuous course of this folded band by tracing its dependence upon the unfolded blocks, against which it has been pressed.

The theory of the permanence of oceans and continents inevitably receives slight consideration from Prof. Suess. He does not trouble us with the *a priori* arguments on this question. He simply tells us the contemporary evidence as to the actual age of the continents. Thus he points out that in the Cretaceous period North America was not; but it had come into existence at the beginning of the Laramie period, and has lasted ever since. Similarly the Indian peninsula and Africa south of the Atlas are remnants of the Mesozoic plateau-continent of Gondwanaland, which has been severed into two by the foundering of the Indian Ocean in late Cainozoic times.

Consideration of Prof. Suess's work inevitably suggests a comparison with that of Lyell. Suessism is sometimes regarded as a rival school to Lyellism. But Suess's essential doctrines are a development of Lyell's views rather than being in direct opposition to them. Lyell, for instance, attacked the belief that volcanoes are craters of elevation; but, in the necessary darkness of the days before Sorby's ingenuity had rendered microscopic petrology possible, he retained his belief in an axis of elevation for the mountain chains. Suess has now taught us that the axes of elevation of mountain chains must follow von Buch's craters of elevation of volcanoes. Even in regard to what is sometimes considered as Prof. Suess's arch heresy—his acceptance of great variations in the ocean level—he is opposed to ultra-Lyellists and not to Lyell. The following passage from the "Principles" shows that, with Lyell, Ordnance Datum was not a fetish:—

"This opinion is, however, untenable; for the sinking down of the bed of the ocean is one of the means by which the gradual submersion of the land is prevented. The depth of the sea cannot be increased at any one point without a universal fall of the waters, nor can any partial depositions of sediment occur without the displacement of a quantity of water of equal volume, which will raise the sea, though in an imperceptible degree even to the antipodes. The preservation, therefore, of the dry land may sometimes be effected by the subsidence of part of the earth's crust (that part, namely, which is covered by the ocean), and in like manner an upheaving movement must often tend to destroy land; for if it renders the bed of the sea more shallow, it will displace a certain quantity of the water, and thus tend to submerge low tracts."

One chief difference between Suess and Lyell is that Lyell was naturally inclined to exaggerate the importance of local earth movements. Prof. Suess, with the benefit of a much wider knowledge than was possible to Lyell, and equal intellectual insight, realises that the geological systems are defined, not by independent local movements, but by changes that are world-wide in scope. Suess's views are not essentially opposed to the uniformity, which Lyell established, in opposition to the preceding belief in catastrophes of extraneous origin. Suess and Lyell both teach us that geological changes are due to causes that are still in action. Geographical evolution, like organic evolution, has not been interrupted by external influences or unnatural catastrophes; but it does not necessarily follow that the rate of progress has been uniform. There have been periods of geographical revolution due to a rush of movements, that relieved stresses produced by long periods of slow change. Such disturbances affect the whole world; and it appears probable that the correlation of strata in distant regions will depend on palæontology only for general homotaxis, and on the events of physical geology for the determination of exact synchronism.

A second difference between Lyell and Suess is that the former attached a, perhaps, exaggerated belief to the importance of denudation in modelling the surface of the globe. His own studies lay in lands wherein denudation has been more powerful than recent earth movements. The sub-title of his "Principles"—"the Modern Changes of the Earth and its Inhabitants Considered as Illustrative of Geology"—shows his point of view. He taught men that the common geographical features of Europe and Eastern America were due to the long-continued operation of slow and still active forces; but he did not fully realise that, elsewhere, the major geographical features are the direct expression of recent disturbances of the crust.

As to the cause of the distribution of these disturbances Prof. Suess has not yet given us his full explanation, and in this volume he rightly held such questions premature. But it is now possible, mainly thanks to his work, to trace one controlling factor in the existing plan of the earth—the alternation of periods of spheroidal recovery due to the earth's rotation, with periods of deformation due to the shrinking of the earth's internal mass. This factor promises the clue to the periodicity of geological events, to the general world-wide correspondence in the geological formations, and to the distribution of the folded bands and foundered blocks of the earth's crust.

J. W. G.

THE "N" RAYS.

A Collection of Papers communicated to the Academy of Sciences, with Additional Notes and Instructions for the Construction of Phosphorescent Screens. By Prof. R. Blondlot. Translated by J. Garcin. Pp. xii+83. (London: Longmans, Green and Co., 1905.) Price 3s. 6d. net.

THE *n*-rays, so called because the first announcement of their existence came from Nancy, have attracted the attention of physicists and physiologists all over the world; but the peculiarity about them is that the phenomena said to be produced by these rays when they fall on a slightly fluorescing screen have been observed chiefly in France by Prof. Blondlot and others of his school, while many experienced observers in Germany, America, and England have wholly failed to obtain a satisfactory demonstration even of their existence. The reason is that the so-called proof of their existence depends, not on objective phenomena that can be critically examined, but on a subjective impression on the mind of the experimenter, who sees, or imagines he sees, or imagines he does not see, a slight change in the degree of luminosity of a phosphorescing screen. It is true that, more than once, a photograph has been taken of such a screen supposed to be unaffected and contrasted with a photograph of the same screen when it was supposed to be affected by the rays, with the result that the patch of luminous surface appears to be a little brighter in the latter case than in the former. Even this photographic evidence, however, is unsatisfactory, as a slight difference in the time of exposure or in the method of development would readily account for the apparent contrast.

Yet, in this little book, we have a reprint of Prof. Blondlot's original papers, in which experimental evidence is adduced, with a wonderful appearance of accuracy in detail, of the polarisation of the rays, of their dispersion, of their wave-length, and of other physical phenomena attributed to them. Prof. Blondlot's experiments are well contrived, and they give every appearance of being arrangements by which accurate data should be obtained; but in every case the ultimate test is the subjective one made on the mind of the observer as to whether a spot of slightly phosphorescent surface becomes more luminous or not. The *n*-rays, according to Prof. Blondlot, are a new species of light, light, however, which only affects the retina with the aid of a fluorescent substance. They traverse many metals, black paper, wood, &c. They cannot pass through sheet lead, but they pass readily through aluminium. They influence not only a fluorescent substance, but the spark of an induction coil. They can be reflected from a polished glass surface or from a plate of polished silver. They have a kinship with well known radiations of a large wave-length. They exist in solar rays. Produced from an Auer burner they can be focused by a quartz lens; the lens itself may even become a source of *n*-rays.

Calcium sulphide can store up the rays, while aluminium, wood, dry or wet paper cannot do so. Ordinary light, when it falls on the retina, causes a more luminous sensation when accompanied by *n*-rays. Bits of wood, glass, rubber, &c., emit the rays when compressed. Bodies in molecular strain, like Rupert's drops, hardened steel, &c., emit the rays. An old knife, found in a Gallo-Roman tomb, equally with a new knife, sends out rays. There are other rays also, which must be called n_1-rays, which are emitted from a Nernst lamp. These diminish the glow of an induction spark. Ethylic ether, "when brought to a state of forced extension," emits the n_1-rays, &c.

To see all these wonderful phenomena the eye must be not only kept in the dark for a considerable time, but it must be specially trained. A. Broca states that in his own case it required practice for six weeks before he could see the effect of the rays. The eye must be adapted not only to darkness, but to very feeble light. The mind must be free, so as to concentrate itself on the observation to be made. These seem to be admirable arrangements for obtaining an illusive subjective impression! It is said that MM. d'Arsonval and Mascart have also observed some of the phenomena. Many other French observers, with less weighty names, have also been cited as witnesses. The general body of men of science are doubtful, as they cannot receive evidence of such a strangely subjective character, while not a few, and the writer places himself in this category, are of opinion that while they do not for a moment reflect on the *bona fides* of the French observers, they hold that these observers have been the subjects either of an illusion of the senses or a delusion of the mind.

JOHN G. MCKENDRICK.

THE SCIENCE OF EDUCATION.

School Teaching and School Reform. By Sir Oliver Lodge. Pp. viii+171. (London: Williams and Norgate, 1905.) Price 3s.

THE science of education is as yet rudimentary and ill-defined. So little has it developed, indeed, that many schoolmasters deny its existence. An art of education they recognise, and that they claim to practise. Teachers, it is urged, are born, not made, and professional training is useless. Yet it is the possibility of the future existence of a complete science of education which is the inspiring belief of the best modern educators. These teachers are now approaching the problems of the class-room and the difficulties of school organisation as subjects for investigation and experiment by scientific methods, and there is every reason for hopefulness in the results which have been obtained in recent years.

The formulation of the fundamental principles of a complete science of education will probably be the work of some great educationist as yet unborn, who will be able from the educational material at his command to extract the essentials and to weave them into living generalisations round which the science will crystallise into an orderly and harmonious whole To the elucidation of such a science many workers

must contribute, and to ensure success men both familiar with science and aware of the difficulties with which teachers have to cope must lend their aid. It is for this reason we welcome these lectures by Sir Oliver Lodge, representing as they do the experience gained by a man of science in many departments of work.

The lectures range over a great variety of topics, and the subjects are presented with but little arrangement. But informal and disconnected though they are, the chapters will cause earnest teachers to reconsider their methods, and strenuously to strive after the improvements adumbrated. Sir Oliver Lodge rightly affirms that the two most important questions for educators to-day are, "What subjects should be selected for teaching?" and "How should they be taught?" But these are precisely the problems teachers have had to face since the Renascence, and we seem little nearer solutions than were the educators of three hundred years ago. A complete answer to the questions propounded will remain impossible until psychology has demonstrated the precise stages in the growth of the immature human intelligence and determined what instruction will assist best each step of such development. For psychology to accomplish this task many carefully planned experiments, carried out by practical teachers imbued with the scientific spirit, are necessary, and the results arrived at must be chronicled and subjected to the most searching criticism.

Mere expressions of opinion will not greatly assist the coming of the new science. What is wanted is investigation. If the man of science will cooperate with the practical schoolmaster, there is no reason why it should not be possible to answer the two vital questions re-stated by Sir Oliver Lodge. But it is imperative that we formulate, after exhaustive discussion, clearly defined problems to be put to the test of experience in schools, and that when we have agreed upon the results we act upon them. It is in this direction that the most fruitful work for education is to be done.

It is unnecessary to summarise the contents of the lectures before us. It is sufficient to say they touch upon the whole field of education. Sir Oliver Lodge is always suggestive, and his *obiter dicta* may be commended to the attention of men of science and school teachers alike. Of all the subjects calling for scientific study and research, the education of the young is the most important. This deserves pre-eminently to occupy the serious attention of all who desire the well being of the human race. A. T. S.

BRITISH BIRDS.

British Bird Life. By W. Percival Westell. Pp. xxxv+338. (London: T. Fisher Unwin, 1905.) Price 5*s*.

THE wearisome procession of books on British birds still drags on—a long train of volumes, all of necessity telling the same tale, and for the most part badly. The laboured apologies which most of these weaklings bring with them show, indeed, that their respective parents realise how slender is the chance of their finding favour even at the hands of a public proverbially long-suffering. Yet still they come.

The present volume endeavours to justify its existence on the plea that "there is need for a work *entirely devoted to those species which nest amongst us year by year* . . ."; and yet a number of species are included in this book which, on the author's own admission, do *not* breed with us year by year. Such are the Canada goose, little owl, golden oriole, hoopoe, and fire-crested wren. To these may be added the white-tailed eagle, spotted crake, roseate tern, and quail! On the other hand, there is reason to believe that the snow-bunting—included in this book—nests annually in Scotland, yet this fact is not even hinted at.

No more trustworthy are the author's statements as to "where our summer migrants spend the winter."

While we heartily agree with much that Mr. Westell has to say on the subject of the relentless persecution which of late years has been meted out to the birds of prey, we must protest against the hysterical notions of justice which he expresses in regard to a case wherein four men were fined thirty shillings apiece for taking a nest of young peregrines "A good dose of the cat," he contends, "or imprisonment without the option of a fine, would probably have had a better effect than a fine of a few shillings"!

As touching this same species, the author gravely assures us that falconry is "a very costly hobby, even the most ordinary Hawks used for falconry costing as much as 10*l*. apiece. They require the most careful attention, and it is difficult to get men qualified to take charge of them under a salary of, say 200*l*. a year."

The photograph purporting to be that of a sparrow hawk is really a picture of a kestrel.

At times Mr. Westell becomes ecstatic, and, blinded by the intensity of his emotions, rushes onwards regardless of obstacles—even of the rules of grammar—as witness the peroration which forms the concluding paragraph of his book:—

"For the good most birds do, for their cheery voices and winning ways, their charming forms and delicate colouring, their beautifully woven nests and exquisite eggs, their fairy-like flight, and other interesting characteristics, I appeal to my readers to study them with a bloodless intention, and to endeavour to learn practical lessons from their industry and devotion to their young; to study them as animate beings, and not as gazed upon as wretched caricatures of bird-life too often found in Museums and collections, and to endeavour to be of some service in specially inculcating and fostering within young and growing children an intelligent love for the bird life of our country"!!

This book is profusely illustrated, partly by photographs, some of which are very pleasing, and partly by "original" drawings, all of which are bad.

W. P. P.

OUR BOOK SHELF.

Riding and Driving. (American Sportsman's Library.) By E. L. Anderson and P. Collier. Pp. xiii+441; illustrated. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1905.) Price 8s. 6d. net.

IN almost all books on subjects connected with animals there is a growing tendency at the present day to introduce something concerning the natural history of the species under consideration. Too often in this country such remarks betray an insufficient knowledge of zoological science on the part of the writer, but this failing is seldom noticeable in American works. In the present volume, truth to say, there is some matter for criticism in Mr. Collier's remarks on the origin of the horse on p. 169, more especially in regard to the sense given to that much abused word "prehistoric." On the other hand, the author furnishes some very interesting information with regard to the early history of the European horse in America. In the first place he refuses to credit the theory that the horses seen by Cabot in La Plata in 1530 were indigenous. Secondly, he shows that the horses which have run wild in Mexico and South America are the descendants of Spanish barbs, and therefore of the same blood as the English thoroughbred. This is very important in view of a fact recently communicated to the present writer by Mr. Yearsley, the well known surgeon, namely, that an Argentine horse living some years ago had a functional "larmier," or tear-gland, on each side of the face.

To review the work before us from its own special point of view would obviously be out of place in this Journal, and it must therefore suffice to say that it appears, so far as we are capable of judging, to maintain the high standard of excellence set in the earlier volumes of the same series. Riding falls to the lot of the first-named of the two authors, while Mr. Collier is responsible for the section on driving. The numerous reproductions from photographs are almost life-like in their sharpness and definition, although it must be confessed that some of them do not convey by any means a pleasing idea of the manners and disposition of the American saddle-horse.

R. L.

Der Oeschinensee im Berner Oberland. By Max Groll. Pp. vi+78; illustrated. (Bern: Haller'sche Buchdruckerei, 1904.)

THIS pamphlet, an extract from the nineteenth volume of the Berne Geographical Society, is the result of a careful study of the Oeschinensee at intervals from 1901 to 1903. Nestling at the foot of the limestone precipices of the Blumlisalp group, about 5200 feet above sea-level, and reflecting like a mirror the snows of their highest peaks, its romantic beauty makes it a favourite resort of visitors to Kandersteg, on the northern side of the Gemmi Pass.

Herr Max Groll's memoir is a valuable contribution to physical geography. After some preliminary information about the position and surroundings of the lake, which lies roughly along the strike of Eocene and Cretaceous limestones, and about other matters of a topographical character, he describes its banks and basin, its dimensions and contents, its variations in level, the transparency, colour, and temperature of its waters, the amount of mud yearly deposited, and adds a note on the literature.

Of these topics, the form of its basin is, perhaps, of most general interest, and of that Herr Groll gives an excellent map and sections plotted from numerous soundings. Its dimensions, of course, vary somewhat with the season, the greatest length and breadth (in summer) being 1750 and 950 metres, when its greatest depth is 56.6 metres; in winter it is about 200 metres less one way and 100 metres the other, and shallower by 15 metres. Under the former conditions its cubical content is estimated to be forty million metres. Its bed deepens at first rather rapidly, a circular diagram of the progressive depth reminding us of an ordinary dinner plate. The ring in which the drop is from 0 to 50 metres is barely an inch wide; the radius of the remainder, which nowhere attains 57 metres, is almost an inch and a half, or, on a rough estimate, about half the lake bed is not less than 50 metres deep. The shallowing is rather more gentle on the western than on the eastern or Blumlisalp side. Near the middle part of this, the 50-metre contour comes rather near the cliffs, those less than 30 metres being closely crowded. This would be yet more conspicuous but for a fan of débris at the south-east angle. The lake, in fact, lies in a kind of corrie at the head of a mountain glen, and it is held up by a natural dam which has been formed by bergfalls from the rocky spurs about a mile below the cliffs at its head. Thus its history is to a considerable extent parallel with that of the Lago d'Alleghe, near Caprile, in the Dolomites.

Manual of the Trees of North America (exclusive of Mexico). By C. S. Sargent. Pp. xxiii+826. (Boston and New York: Houghton, Mifflin and Co., 1905.) Price 6 dollars.

THE manual under notice embodies the most recent, exhaustive, and detailed account of the trees of North America (exclusive of Mexico). It cannot fail to be of the greatest value to students of botany and forestry, as it brings into available form all the information concerning the trees of North America which has been gathered at the Arnold Arboretum during the last thirty years. As the author points out in the preface, there is probably no other region of equal extent where the indigenous trees are so well known as those of North America, but in spite of this fact much investigation yet remains to be done as regards their sylvicultural requirements, and also the diseases to which they may be liable.

The object of this volume is to stimulate further inquiry into the cultivation requirements and diseases of forest trees. The classification adopted is that of Engler and Prantl's "Die naturlichen Pflanzenfamilien." At the beginning of the book a synopsis of the families of the plants described is given. This is followed by a very useful analytical key to the families based on the arrangement and character of the leaves, which will enable the student readily to determine the family to which any North American tree belongs. In the text a full description of each family is given, and also a conspectus of the genera based on their more salient and easily made out contrasting differences. Under each genus a similar conspectus of the species is given by which the exact name of the tree may be finally determined.

The frontispiece consists of a map of North America showing the eight principal regions of arborescent vegetation, each of which is indicated by a letter, and in the conspectus above referred to a letter occurs after the name of each species, thus indicating the region in which the tree grows. This is a further aid in determining any given species provided the region from which it comes is already known.

A valuable feature of the book is the numerous illustrations, which number between six and seven hundred, from drawings by Mr. Faxon.

LETTERS TO THE EDITOR.

Number of Strokes of the Brush in a Picture.

THE number of strokes of the paint brush that go to making a picture is of some scientific interest, so I venture to record two personal experiences. Some years ago I was painted by Graef, a well known German artist, when, finding it very tedious to sit doing nothing, I amused myself by counting the number of strokes per minute that he bestowed on the portrait. He was methodical, and it was easy to calculate their average number, and as I knew only too well the hours, and therefore the number of minutes, I sat to him, the product of the two numbers gave what I wanted to learn. It was 20,000. A year and a half ago I was again painted by the late lamented artist Charles Furse, whose method was totally different from that of Graef. He looked hard at me, mixing his colours the while, then, dashing at the portrait, made his dabs so fast that I had to estimate rather than count them. Proceeding as before, the result, to my great surprise, was the same, 20,000. Large as this number is, it is less than the number of stitches in an ordinary pair of knitted socks. In mine there are 100 rows to each 7 inches of length, and 102 stitches in each row at the widest part. Two such cylinders, each 7 inches long, would require 20,000 stitches, so the socks, though they are only approximately cylinders, but much more than 7 inches long, would require more than that number.

The following point impressed me strongly. Graef had a humorous phrase for the very last stage of his portrait, which was "painting the buttons." Thus, he said, "in five days' time I shall come to the buttons." Four days passed, and the hours and minutes of the last day, when he suddenly and joyfully exclaimed, "I am come to the buttons." I watched at first with amused surprise, followed by an admiration not far from awe. He poised his brush for a moment, made three rapid twists with it, and three well painted buttons were thereby created. The rule of three seemed to show that if so much could be done with three strokes, what an enormous amount of skilled work must go to the painting of a portrait which required 20,000 of them. At the same time, it made me wonder whether painters had mastered the art of getting the maximum result from their labour. I make this remark as a confessed Philistine. Anyhow, I hope that future sitters will beguile their tedium in the same way that I did, and tell the results. F. G.

The Hydrometer as a Seismometer.

A SHORT time ago (NATURE, May 25) I directed attention to a misconception which seemed to prevail among seismologists as to the behaviour of a spirit-level. It may perhaps be useful to point out another fallacy, also of an elementary hydromechanical nature, involved in some of the unsuccessful attempts to record vertical motion.

It was first proposed by Dr. Wagener, we read,[1] to record vertical disturbance by means of a floating buoy free to rise and fall in a vessel of water. The buoy was to provide a steady point when the vessel suffered a vertical disturbance. The device was improved, we are told, by Prof. Thomas Gray, who gave the buoy the form of a hydrometer with only a slender stem projecting above the surface of the water. Prof. Milne experimented with both forms; but even with the hydrometer form, adjusted to a state of the most sluggish stability, several earthquakes left no record of vertical motion. The instrument was abandoned as not sufficiently powerful to be self-registering.

But the theory involved in these attempts is entirely fallacious. Any body, be it buoy or hydrometer, floating in liquid, suffers no displacement whatever relatively to the liquid when the containing vessel is moved vertically. The whole moves as one rigid system. More generally, it may be claimed that any system which is in statical equilibrium, and which would remain undisturbed despite a change in the value of gravity, may suffer a vertical displacement of its supports without any relative disturbance of its parts. The whole of such a system moves as if rigid when displaced vertically. Of such a kind is the hydrometer floating in the vessel filled with liquid; of the same kind, also, is a common balance with equal weights in the two scale-pans. These two systems present a true dynamical analogy, and are equally useless for detecting vertical disturbance. A spring supporting a load, on the other hand, or any form of apparatus the potential energy of which is partly elastic, is not of this class, and is available as a seismometer for vertical motion. It would seem as though a false analogy between the hydrometer and the spring balance had led to the fallacy in question.

The spirit-level (if my previous contention is conceded) is sensitive alike to each of two kinds of disturbance between which it was expected to discriminate. The hydrometer, on the other hand, is insensitive to the very disturbance which it was designed to record. The freezing of the water, indeed (contemplated as an inconvenient contingency with the proposed instrument), would, very precisely, make no difference at all in its behaviour. The instrument has, it is true, been long superseded; but the false principle involved remains as a source of grave confusion for the unwary reader of seismological writings.

It may be remarked that violent earthquakes have been known to damage the rigging of ships in a neighbouring harbour, and to jerk guns from the decks, without any visible movement of the water. Assuming the correctness of the view now urged, a sudden alteration of sea-level would completely account for this. The ship is not in any way spring-borne for such a displacement, but may be subjected to a vertical impulse of any degree of severity.

It should be added, also, that a severe shock of earthquake is credited[1] with having disturbed a hydrometer instrument to the extent of 1·1 mm. If the onus of explanation rests with me, I can only suggest that the effect (if really caused by vertical motion at all) may perhaps have been due to the elasticity of the walls of the containing vessel or of the hydrometer. G. T. BENNETT.

The Pressure of Radiation on a Clear Glass Vane.

IN an article on "The Elimination of Gas Action in Experiments on Light Pressure," read before the American Physical Society in December, 1904, and published in the *Physical Review*, May, the writer made the following statement:—"A thin vane of clear glass, accurately vertical and mounted radially, may be used to advantage to demonstrate light pressure. If the light has been filtered through several thicknesses of glass there will be but little absorption by the thin vane and its two surfaces will be warmed nearly equally. Consequently the radiometric effect will be small. The reflection of the radiation at the two surfaces will make a difference of about 16 per cent. between the energy in front of and behind the vane. Hence the light pressure will be about one-sixth of that due to the same light beam falling upon a black surface. The throws for such a vane had only about a ten per cent. variation in a range of air pressures from about 10 mm. to 200 mm. of mercury."

Although a large number of observations had been taken on both clear glass and silvered glass vanes, the data were not published at that time. It was then felt that the elimination of gas action was the important point, and the final statement in the paragraph quoted, that the throws for such a vane had only a 10 per cent. variation in a range of air pressures from about 10 mm. to 200 mm. of mercury, was considered sufficient experimental evidence that gas action had been eliminated.

Since this paper appeared, the writer has learned that there is a difference of views among mathematical physicists concerning the pressure of radiation on a non-absorbing medium. On this account he has gathered

together the original data in order to compare the light pressure upon a vane of clear glass with that upon a silvered surface.

The experiment may be here recalled. A torsion balance carrying a thin vertical glass vane, $14 \times 10 \times 0 \cdot 1$ mm., silvered on one side, was suspended in a bell jar, and the air was pumped out until the pressure was about 40 mm. of mercury. A beam of light was thrown upon this vane at a definite distance from the rotation axis, and by turns on each side of it. The deflections were read by a telescope and scale. A Nernst lamp was used as a source, the intensity being given by a precision wattmeter. The balance was then turned through 180° by the rotation of the external control magnet, and readings were again taken. The mean was proportional to the pressure of the incident and reflected beam. The mean reflection coefficient of air-silver and air-glass-silver for the radiation used has been found to be 85 per cent. The pressure, according to Maxwell's theory, should therefore be 1·85 times that due to the incident beam. The throw obtained (containing certainly less than 1 per cent. of gas action) was 22·8 divisions. Hence the pressure of the standard beam upon a black surface would be $22 \cdot 8 \div 1 \cdot 85$ or 12·4.

The balance was then taken from the bell jar, the silver removed from the vane, and the glass surface cleaned. The balance was then replaced, and the air pumped out as before. The deflections were small, only about 2 mm., and therefore could not be read to a greater accuracy than 5 per cent. The throw obtained for standard lamp was 2·1 divisions (the mean of forty observations at four different air pressures).

The normal reflection coefficient of glass ($\mu = 1 \cdot 52$) for this kind of radiation is 4·1 per cent. The amount reflected from the two surfaces is approximately 8·2 per cent. Hence the energy per unit volume in front of the glass is about 1·082 times that of the incident beam, and that behind the vane (since the absorption is negligible) is 0·918 times that of the incident beam. The former quantity is greater than the latter by 16·4 per cent. of the energy of the incident beam. Assuming that the pressures on the front and back surfaces of the glass are proportional to the energies per unit volume, the pressure of the standard beam upon a black surface would be $2 \cdot 1 \div 0 \cdot 164$ or 12·7. The agreement between this result and the similar result obtained from the silvered surface shows that light passing through a plate of glass exerts pressures upon the surfaces equal to the difference between the energies per unit volume in front of and behind these surfaces.

The Habits of Testacella.

UNTIL reading Mr. Latter's letter in this week's NATURE I was unaware that it was not a matter of common knowledge that Testacella appears on the surface during heavy rains. My garden is liable to be flooded, as also, unhappily, is much of this neighbourhood, in spring and late autumn. After the water has stood for a few days the ground is covered by hundreds of these slugs, which leave their burrows and try to find dry quarters. They can survive, however, a week's immersion. In June, 1903, when much of the Thames valley was flooded, I collected a number of these slugs for various malacological friends. In normal circumstances they live at such a depth as never to be unearthed during garden operations.

NATURE AND MAN.

PROF. LANKESTER in his Romanes lecture began by a statement of the theory of evolution, directing attention to unwarranted inferences commonly drawn by clever writers unacquainted with the study of nature. He described how the change in the character of the struggle for existence, possibly in the Lower Miocene period, which favoured an increase in the size of the brain in the great mammals and the horse, probably became most important in the development of man. The progress of man cut him off from the general operation of the law of natural selection as it had worked until he appeared, and he acquired knowledge, reason, self-consciousness, and will, so that "survival of the fittest," when applied to man, came to have a meaning quite different from what it had when applied to other creatures. Thus man can control nature, and the "nature-searchers," the founders of the Royal Society and their followers, have placed boundless power in the hands of mankind, and enabled man to arrive at spiritual emancipation and freedom of thought. But the leaders of human activity at present still attach little or no importance to the study of nature. They ignore the penalties that rebellious man must pay if he fails to continue his study and acquire greater and greater control of nature.

Prof. Lankester did not dwell upon the possible material loss to our Empire which may result from neglect of natural science; he looks at the matter as a citizen of the world, as a man who sees that within some time, it may be only 100 years, it may be 500 years, man must solve many new problems if he is to continue his progress and avert a return to nature's terrible method of selecting the fittest. It seems to us that this aspect of the question has never been fully dealt with before. Throughout Huxley's later writings the certainty of a return to nature's method is always to be felt. Prof. Lankester has faith in man's power to solve those problems that seem now to be insoluble, and surely he is right.

The dangerous delay now so evident is due to the want of nature knowledge in the general population, so that the responsible administrators of Government are suffered to remain ignorant of their duties. Prof. Lankester shows that it is peculiarly in the power of such universities as Oxford and Cambridge, which are greatly free from Government control, to establish a quite different state of things from that which now obtains in England. He says:—"The world has seen with admiration and astonishment the entire people of Japan follow the example of its governing class in the almost sudden adoption of the knowledge and control of Nature as the purpose of national education and the guide of State administration. It is possible that in a less rapid and startling manner our old Universities may, at no distant date, influence the intellectual life of the more fortunate of our fellow citizens, and consequently of the entire community." Considering Oxford more particularly, and speaking for others as well as himself, he says:—"The University of Oxford by its present action in regard to the choice and direction of subjects of study is exercising an injurious influence upon the education of the country, and especially upon the education of those who will hereafter occupy positions of influence, and will largely determine both the action of the State and the education and opinions of those who will in turn succeed them." As to Greek and Latin studies, he says:—"We have come to the conclusion that this form of education is a mistaken and injurious one. We desire to make the chief subject of education both in school and in college a knowledge of Nature as set forth in the sciences which are spoken of as physics, chemistry, geology and biology. We think that all education should consist in the first place of this kind of knowledge, on account of its commanding importance both to the individual and to the community. We think that every man of even a moderate amount of education should have acquired a sufficient knowledge of these subjects to enable him at any rate to appreciate their value, and to take an interest in their progress and application to human life." He points out that it is only in the

last hundred years that the dogma of compulsory Greek and the value of what is now called a classical education has been promulgated. Previously, Latin was learnt because all the results of the studies of natural philosophers were in that language.

It is evident that Prof. Lankester includes in his study of nature the study of intellectual and emotional man through history, biography, novels, and poetry, but we think that he made a tactical mistake when he neglected to state this clearly. It seems to us that besides the study of nature, the most important thing in a child's education is to make him fond of reading in his own language, for this leads to a future power to make use of books and self-education for the rest of his life. When Prof. Lankester doubts the value of the study of history he is evidently doubting the value of that study as carried on at Oxford, and surely no person who has read the scathing criticism of Prof. Firth will disagree with him. When he speaks of a reform being possible, it may be that he is taking into account a movement of which but little is known outside Oxford itself, the growing indignation of the average undergraduate at being made to pay extravagant sums of money for tuition which is mischievous.

The readers of NATURE are well acquainted with the views put forward in this address. Huxley and many others, dwelling, perhaps, more upon material loss to our Empire, have published them over and over again, but we do not think that anybody has ever presented them with so much grace of style or so much of an endeavour to secure the goodwill of his audience as Prof. Lankester. But, alas! we fear that this fine address will share the fate of many others!

When, thirty-three years ago, Japan began her new career, there were a few people like Ito clever enough to see and say that the study of ancient classics alone, to the neglect of the study of nature, meant ruin to the country; but such ideas would never have been adopted had not Japan been in deadly peril. All the nations of Europe bullied and insulted her, and it was only their mutual jealousies which saved her from complete subjugation. In the presence of that peril the pedants held their peace, and everybody saw the necessity for an immediate, radical reform. In time nature was studied by every child in Japan, and in consequence scientific methods of thinking and acting have permeated the whole nation. All ancient and modern European literature is open to the Japanese who knows English, and English is the one language other than Japanese which every cultured man must know. In the matter of self-protection, anyone can see the result. Because the Japanese have studied nature their scientific officers and men have marched or sailed to victory in every engagement; their statesmen will do exactly what is best for Japan in the negotiations for peace; their country will quietly take its place as one of the first-class Powers of the world, and every person who knows anything about Japan is quite sure that ambitious, wrong-headed schemes of conquest are altogether impossible to the scientific minds of the Japanese.

If Japan had not been in great danger we know that she would not have taken to nature-study, and some of us think that it may need a state of danger in England to produce the necessary desire for reform. The South African muddle was worried through, and almost everybody seems to think that all such muddles may also be worried through, but some of us think that we may not always be so lucky. Danger is close enough even now, and we can only hope that if it becomes great it may grow slowly enough to let us learn something from the object lesson which is being given us day by day in the news from Russia and the Far East.

Fain would we hope that Oxford will pay attention to what has been said by one whom some of us regard as her cleverest son; but, alas! we have no such hope. Oh, Shade of Clough, how can we help saying that "the struggle nought availeth" when your own best admirers seem unable to think for themselves?

JOHN PERRY.

A LIFE'S WORK IN THE THEORY OF EVOLUTION.[1]

IN this elaborate and carefully written treatise the veteran biologist of Freiburg has brought together and presented in connected form the fruit of his life-long investigation of the principles and methods of organic evolution. It would be an easy matter to show—indeed, the author admits as much with perfect candour—that his present standpoint differs in many important respects from that adopted by him at former periods of his career. The fact that Weismann has more than once shifted his ground has often been brought against him as a kind of reproach—we think with scant justice; for in a subject like the present, where new facts come crowding upon us almost daily, it is unreasonable to expect that a far-reaching theory should at once attain finality. If the author of such a theory should be willing to recognise that some parts of it become untenable and others require modification in the light of fresh discoveries, this should be reckoned to his credit rather than otherwise. The practice of putting forward ill-considered and hasty views deserves severe condemnation; but it is characteristic of our author that even his boldest speculations rest for the most part on a basis of observed fact, and that he has always honestly striven to render his theory consistent both with itself and also with the new facts that have from time to time come under the observation of other investigators. Moreover, his plan of, so to speak, taking the scientific world into his confidence, and enabling his colleagues to follow the workings of his own mind, has not only added greatly to the interest of his contribution to the biological thought of our time, but has acted also as a powerful stimulus to fellow-workers in the same field. So much may fairly be said, whether his final conclusions meet with general acceptance or the reverse.

The first eleven chapters of the present book traverse familiar ground. Starting with a brief historical account of evolutionary theory up to and including the work of Darwin and Wallace, they proceed to a more detailed discussion of such branches of the subject as the coloration of animals, mimicry, instinct, symbiosis, protective adaptations in plants, the origin of flowers, and sexual selection. These are well-worn topics, but their treatment is interesting and by no means trite. Next comes a discussion of Roux's suggestion of the "Kampf der Theile" which strikes us as somewhat of an excrescence on the general structure of the treatise. The existence of a metabolic response to functional stimulus is undeniable, but we do not think that either Roux or Weismann has plumbed the matter to the bottom, and the latter author's use of the term "selection" in this connection appears to involve some overstrain of language.

[1] "Vorträge über Deszendenztheorie gehalten an der Universität zu Freiburg im Breisgau." By Prof. August Weismann. Second revised edition. 2 vols. Pp. xii + 340; vi + 344. (Jena: Gustav Fischer, 1904.) Price 10 marks.

"The Evolution Theory." By Prof. August Weismann. Translated with the author's co-operation by Prof. J. Arthur Thomson and Margaret R. Thomson. 2 vols. Pp. xvi + 416; iv + 405; illustrated. (London: Edward Arnold, 1904.) Price 32s. net

Chapters on reproduction and the process of fertilisation in both unicellular and multicellular organisms lead us on to a copious exposition of the author's theory of the germ-plasm and its constitution, with the building up of the assumed ultimate vital units or "biophors" into the successive complexes of "determinants," "ids," and "idants." After a discussion of the facts brought to light by the labours of the "Entwicklungsmechanik" school, and a fairly full notice of recent work on regeneration in its relation to the germ-plasm hypothesis, we come to what is in many respects the strongest part of the book, the refutation, namely, of the Lamarckian view of the transmissibility of functional modifications. Here Weismann has always been at his best, and to him undoubtedly belongs the credit of having awakened and sustained so fresh and vigorous a body of opinion in reference to this point as virtually to have created one of the most important epochs in the history of evolutionary doctrine. The two next chapters deal with the author's hypothesis of "germinal selection," as to which it may be sufficient to remark that, however ingenious and interesting the theory may be as an attempt to explain the chief phenomena of variation, it is as yet far from having reached the stage of verification. In the succeeding chapters, which deal with inbreeding, parthenogenesis, and reproduction, both sexual and asexual, it is interesting to observe that Weismann has considerably modified his standpoint with reference to amphimixis, his present view approximating in some degree to that advanced several years ago by Haycraft. This section is preceded by a discussion of the "biogenetic law" of Haeckel, and is followed up by chapters on the influence of the environment and of isolation in the formation of the specific type, together with the various causes of extinction.

The book concludes with some theoretical considerations on the subject of spontaneous generation, and a final vindication of the principle of selection, the dominance of which principle over all the categories of vital units may be taken as the key-note of the entire treatise.

It will be seen that the ground covered by this work is very extensive. Though most of the topics dealt with are considered by the author chiefly or solely with an eye to his theory, his treatment never lacks interest, and the result is worthy of his high reputation. There are some points as to which we should have welcomed a more thorough discussion, and others on which we confess to remaining unconvinced for reasons *quas nunc perscribere longum est*; but it would be ungrateful not to acknowledge to the full the immense services rendered to biological science by the stimulating labours in the domain both of theory and practice of which this book is a monument.

The illustrations are for the most part excellent. Of the two here reproduced, the first serves to illustrate the basis of one of the chief arguments brought forward by Weismann, as also by Strasburger and O. Hertwig, in favour of regarding the nuclear chromatin as the true hereditary substance, viz. the numerical equality of the chromosomes and the disparity in amount of the cell-protoplasm in the generative products of the two sexes. The second (from Fischer) supplies evidence of the possibility of certain external conditions, in this case temperature, influencing the germ-plasm even while contained within the body of the parent.

We have little space left for detailed criticism, but must point out that by some unaccountable oversight the letterpress of plates i. and ii. contains several serious errors—patent at once to the trained entomologist, but calculated to mislead the general reader. These mistakes appear uncorrected in the English translation, where also, as if to make confusion worse confounded, "die folgende Art" (plate ii., Fig. 20) is rendered "the *foregoing* species." Fortunately, however, the lapses in question are not of

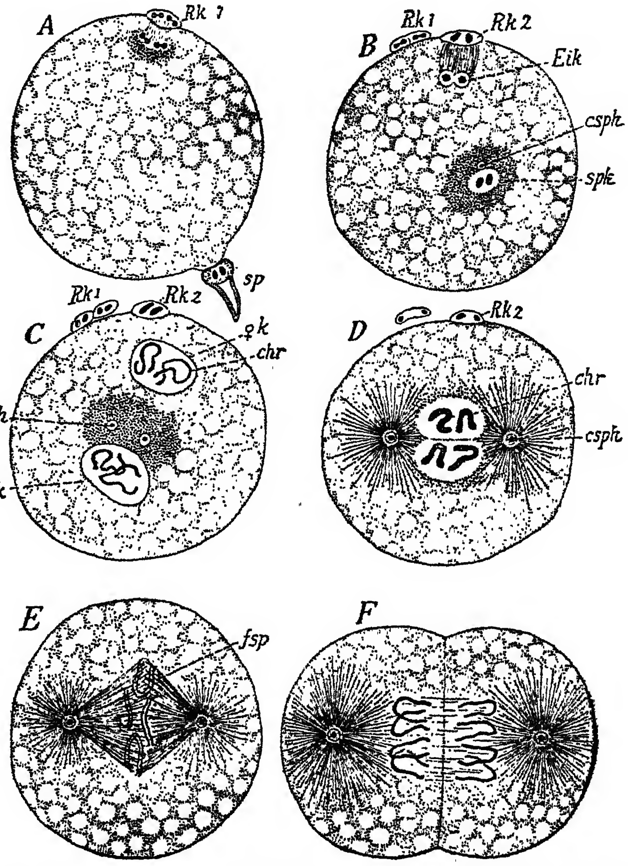

FIG. 1.—Process of fertilisation in *Ascaris megalocephala*. *Rk* 1, *Rk* 2, first and second polar body; *sp*, spermatozoon with two chromosomes, a protrusion of the egg-protoplasm is meeting it; *Eik*, reduced nucleus of the ovum; *spk*, nucleus of spermatozoon; ♂ *k*, ♀ *k*, sperm nucleus and ovum nucleus, each with two chromosomes (*chr*); only the male nucleus has a centrosphere (*csph*), which in *C* has already divided into two; *fsp*, segmentation spindle. From Weismann's "Evolution Theory." Translated by Prof. and Mrs. Thomson.

a nature to impair the value of the argument which the figures are meant to illustrate.

Other slips in the translation are plainly due to the fact that the translators are unfamiliar with portions of the subject-matter, as in vol. ii., p. 348, where the point of the argument is blunted by the rendering of "Nachtfalter" as "butterfly"; such imperfections, though they should be remedied in a new edition, are of little real importance. More serious is a mistranslation, or perhaps a misprint (vol. i., p. 290) by which the words of the original, "in welchem die eigentliche Chromatinsubstanz nur in vielfacher Zertheilung enthalten ist," are perverted into a statement which is almost grotesquely incorrect.

Again, on p. 304 of the same volume, an entirely wrong meaning is given to a sentence by the failure of the translators to make it clear that "wenn es nothwendig wäre" must refer, not to "fertilisation," but to the "limitation of polar divisions." On p. 136 (vol. ii.) the sense of the original is obscured by the inadequate rendering of "dann" as the enclitic "then." *Chaerocampa* (for *Choerocampa*) is found in the original; the translators, however, are responsible for "Cœnogenesis."

But in spite of these and other blemishes of a like nature, the translators are to be congratulated on having performed their difficult task with skill and success, the result being a work which, in its English

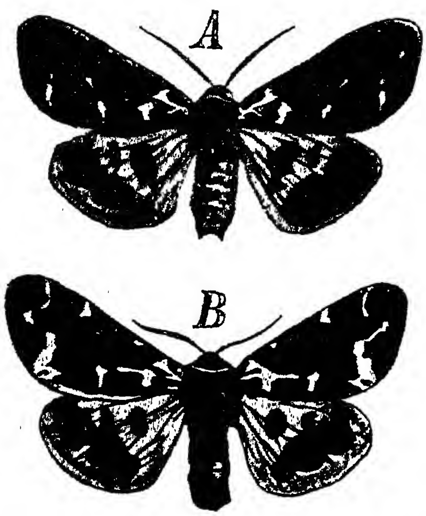

Fig. 2.—*A*, an aberration of *Arctia caja*, produced by low temperature. *B*, the member of its progeny most divergent from the normal. *B*, though reared at the ordinary temperature, is aberrant in the same direction as its parent. no less than in its German dress, will be read with extreme interest and with the greatest sympathy and respect for its indefatigable author. F. A. D.

DR. WILLIAM THOMAS BLANFORD, F.R.S.

The tidings of Dr. Blanford's death will be received with sorrow among men of science all over the world. His many-sided accomplishments had given him a notable place among geologists, geographers, palæontologists, and zoologists, and his gentle, kindly, unassuming nature had gained him an abiding place in the affectionate regard of all who came to be associated with him. Born on October 7, 1832, in London, he early developed a taste for scientific pursuits, and was accordingly sent to the Royal School of Mines, Jermyn Street, where he distinguished himself as a student, under De la Beche, Playfair, Edward Forbes, Ramsay, Smyth, and Percy. From London he passed to the famous mining academy at Freiberg. Having thus obtained an excellent training, he was, in 1855, appointed to the Geological Survey of India under its founder, Thomas Oldham. For some twenty-seven years he continued to devote his energies to Indian geology, making wide acquaintance with the rocks and scenery of the great Dependency, and enriching the publications of the Survey with maps and descriptive memoirs. Had he chosen to remain longer in the service, he would soon have been placed at its head; but in 1882 he resolved to retire on the pension which he had well earned, and to establish himself in London. Among the great services which he rendered to science during his stay in India, perhaps the most important was the preparation, in concert with his colleague, H. B. Medlicott, of a "Manual of the Geology of India." This invaluable treatise gave for the first time a succinct general view of the geological structure and history of the whole country. It has taken its place as one of the classic text-books of the science.

While attached to the Indian Survey, Dr. Blanford's proved ability led to his being employed in several missions or expeditions. Thus when, in 1867, preparations were made in India for the dispatch of an armed force against Theodore of Abyssinia, he was selected as geologist to accompany the Army. The wisdom of this selection was well proved by the excellent volume in which he gave the results of his observations during the march to Magdala and the return to the coast. Again, in 1872, he accompanied the Persian Boundary Commission, and his notes of this journey were embodied in another valuable book.

During his travels in India and beyond it, Dr. Blanford did not confine himself to the study of the rocks, but always kept a keen eye on the wild animals of each region. His published journals showed him to be as capable a zoologist as he was a geologist. Indeed, during the later years of his life his main scientific work lay amidst the fauna of British India, in regard to which his published memoirs were recognised as the chief authority on the subject. His wide experience as a traveller over the surface of the earth likewise enlisted his sympathies with geographical exploration, and made him a valued member of the council of the Royal Geographical Society.

In his writings there is often a suggestiveness or prescience that shows how keen was his insight, how far-reaching his grasp of scientific problems, more especially of those in which questions of zoology and geology were intermingled. Some of his papers in which he unfolded his views on these subjects are well deserving of attentive study. His address to the geological section of the British Association at the Montreal meeting in 1884, and his presidential discourses to the Geological Society in 1889 and 1890, may be cited as examples of his characteristic manner of treatment.

Dr. Blanford's high qualities as a man of science were fully recognised by his contemporaries. He was early elected into several of our leading scientific societies, and was chosen as a member of their councils. He received the Wollaston medal of the Geological Society and a Royal medal of the Royal Society. A few years ago, in recognition of his services to Indian science, he was made a Companion of the Order of the Indian Empire. Up to the end he continued to interest himself in the affairs of the societies with which he was connected. For years he had been treasurer of the Geological Society, and he attended the council meetings to within a few weeks before his death. His colleagues at the council board then saw with regret that his health was obviously failing, but they did not anticipate that they were never again to see his familiar face among them. A few weeks ago he was asked by the council of the Royal Society to write for them an obituary notice of his old friend and colleague, Medlicott, who had recently died. He complied with this request, and it proved to be his last piece of work. The printed proofs of his manuscript were sent to him, but before they could reach him he had become too ill to look at them. After a short illness he passed away on the morning of Friday, June 23,

in the seventy-third year of his age. He was laid to rest on Tuesday last in Highgate Cemetery, every society with which he was associated sending representatives to his funeral, while among the mourners were some of his old colleagues in India.

A. G.

NOTES.

THE Civil List Pensions granted during the year ended March 31 show more generous recognition of the claims of science than has usually been the case. The list includes the following pensions:—1904, August 8.—Mr. W. F. Denning, in consideration of his services to the science of astronomy, 150*l*. August 8.—Miss Elizabeth Parker, in recognition of the services rendered to science as an investigator by her late father, Mr. W. Kitchen Parker, F.R.S., 100*l*. August 8.—Lady Le Neve Foster, in consideration of the services rendered to mining science by her late husband, Sir Clement Le Neve Foster, F.R.S., and of the fact that his death was due to the effects of poisoning by carbonic oxide gas while carrying out his official duties, 100*l*. 1905, January 17.—Dr. J. G. Frazer, in recognition of his literary merits and of his anthropological studies, 200*l*. March 22.—The Rev. Lorimer Fison, in recognition of the originality and importance of his researches in Australian and Fijian ethnology, 150*l*. March 22.—Dr. W. Cramond, in consideration of his antiquarian researches, more particularly in connection with the ecclesiastical and burghal history of Scotland, 80*l*. March 22.—Miss L. C. Watts and Miss E. S. Watts, in recognition of the services of their late father, Mr. Henry Watts, to chemistry, 75*l*. It is satisfactory to record these tributes of national regard for lives devoted to the advancement of knowledge; and we congratulate the Government upon the great improvement which this year's list shows as regards the acknowledgment of the services rendered to the State by scientific workers.

WE regret to learn that Prof. von Tomek, president of the Imperial Bohemian Academy of Sciences at Prague, died on June 12 in the eighty-eighth year of his age.

SIR JOHN WOLFE BARRY, K.C.B., F.R.S., has been elected to succeed the late Mr. James Mansergh, F.R.S., as chairman of the Engineering Standards Committee.

THE annual conversazione of the Society of Arts will be held in the gardens of the Royal Botanic Society, Regent's Park, on Tuesday next, July 4.

THE International Institute of Sociology has accepted the invitation of the Sociological Society to hold its next congress in London in the summer of 1906. A general committee has been appointed to promote the success of the congress. Lord Avebury is the chairman of the committee, and Mr. David Mair the secretary for the time being.

THE Guy medal in silver has been awarded by the Royal Statistical Society to Mr. R. Henry Rew for his work in connection with the preparation of the reports of the special committee appointed by the society to investigate the production and consumption of meat and milk in the United Kingdom, and for his paper entitled "Observations on the Production of Meat and Dairy Products."

AMONG those who lost their lives in the railway disaster at Mentor, Ohio, on June 21 was Mr. Archibald P. Head, a brilliant young engineer and senior partner in the firm of Messrs. Jeremiah Head and Sons, of Westminster. Mr. Head was the author of several valuable papers on mining and metallurgy contributed to the Institution of Civil Engineers, the Iron and Steel Institute, and the Society of Arts.

IT is announced in the *Times* that the Board of Trade and the Trinity House have concluded a contract with Marconi's Wireless Telegraph Company (Limited) providing for the equipment of lightships with Marconi wireless telegraph installations. This arrangement will enable the lightships to communicate with the shore and with one another by wireless telegraphy for the ordinary purposes of the lightship service, and also to report ships in distress.

A REUTER telegram from Paris reports that an International Congress on Colonial Agriculture was opened there on June 22, Great Britain, Holland, Germany, Italy, Portugal, the United States, Mexico, and Brazil being represented. The members of the congress decided to form an international committee for the study of all questions relating to agricultural science and colonial industries. An organising committee, with headquarters in Paris, under the chairmanship of M. de Lanessan, has been formed.

TOWARD the close of the fourth International Ornithological Congress, an account of which appeared in our issue of last week (p. 177), a party of members paid a visit on June 20 to Cambridge. They were received by Prof. Newton, who had arranged several exhibits for the benefit of the visitors. These included a case of great auks' eggs and a selection of letters, papers, and books from Prof. Newton's library. A catalogue of these documents and books, some of them belonging to the fifteenth century, was distributed among the visitors, as was a leaflet on Legaut's giant bird by Prof. Newton explaining its origin and species. A pamphlet by Dr. Gadow on the effects of insularity, illustrated by birds of (*a*) Madagascar and Mascarene Islands, and (*b*) the Sandwich Islands, was also circulated to explain the exhibits arranged in the lecture room of comparative anatomy. A visit to the museums having been concluded, a dinner was given to Prof. Newton in the hall of Magdalene, after which Dr. Fatio in a cordial speech referred to Prof. Newton as "the father of ornithology." The congress concluded on June 21 with a visit to Flamborough Head.

DR. J. CHARCOT gave an account of his expedition to Antarctic regions before the Royal Geographical Society on Monday. The general programme of the expedition was to survey the north-west coast of the Palmer Archipelago (Hoseason, Liége, Brabant, and the Antwerp Islands); to study the south-west entrance to the Gerlache Strait, wintering as far south as was practicable, to make excursions in spring, and in summer to continue the exploration of Graham Land, with the view of elucidating the Bismarck Strait, and follow the coast as far as Alexander I. Land; in a word, to continue the labours of the Gerlache and Nordenskjöld expeditions. The expedition left Buenos Ayres in the *Français* (245 tons) on December 23, 1903, reached Smith Island (South Shetlands) on February 1, 1904, and after coasting for a few weeks was compelled by ice to return to Wandel Island, where it wintered. The temperature varied much and suddenly; the lowest was $-30°.4$ F., but a rise from $-22°$ F. to $+26°.6$ F. in a few hours was not uncommon, and was always followed by violent gales from the north-east, which broke up the ice between Wandel and Hovgaard Islands, and so prevented any move being made, in spite of many efforts. In December, 1904, a channel was made, and the *Français* returned to Wincke Island, which had been visited before

the winter set in. In January the vessel was turned north again past the Biscoe Islands, the expedition completing its survey as it went, and finally reached Puerto Madryn on March 4. Dr. Charcot expressed himself thoroughly satisfied with the results of the work of the expedition in hydrography, astronomy, biology, the measurement of tides, the analysis of colour and density of sea-water, and gravity, which was measured by means of one of M. Bouquet de la Grye's comparison pendulums. The exterior contour of the Biscoe Islands has been fixed and their breadth determined; the survey of the exterior coasts of the Palmer Archipelago completes the geography of that region, and the bearings of Alexander I. Land have been found by astronomical observation.

THE International Congress of Mining and Metallurgy at Liége, which began on June 25, and will continue until July 2, is proving a most successful gathering. Nearly fifteen hundred members have registered, and an attractive programme of papers, visits and excursions, and social functions has been arranged. Mr. Alfred Habets was elected president, and the official representatives nominated by seventeen foreign Governments were elected honorary presidents. Great Britain, though not included in this list, was represented by a strong contingent of members of the Iron and Steel Institute, and by a number of leading mining engineers. The congress was divided into four sections, dealing respectively with mining, metallurgy, applied geology, and mechanics. In the metallurgical section the first paper read was by Mr. R. A. Hadfield, who gave an account of his recent investigations of the properties of steel at the temperature of liquid air. Papers were also read on the influence of arsenic and titanium on pig iron, on the use of coals poor in agglutinating material for the manufacture of coke, and on the cutting of metals by oxygen. In the mining section several papers on shaft-sinking were read, and in the applied geology section attention was chiefly devoted to the recent coal discoveries in the north of Belgium.

WE regret to see the announcement in the *Times* that Sir Augustus Gregory, K.C.M.G., the Australian explorer, died a few days ago. Sir Augustus was born in Nottinghamshire in 1819, and entered the Civil Service of Western Australia in 1841. Five years later he began the series of explorations which were afterwards to make him famous. In 1846 he started with two brothers into the interior from Bolgart Spring, but their eastward progress was stopped by an immense salt lake which compelled them to turn north-west. The deviation led to the discovery by the party of some fine seams of coal in the country at the mouth of the Arrowsmith. Two years later he was sent northwards to explore the Gascoyne River, and he succeeded in reaching a point 350 miles north of Perth. A third exploring expedition was undertaken in 1855, this time under the auspices of the Royal Geographical Society of London. The expedition had the dual object of exploring the interior and of searching for traces of the lost explorer Leichhardt. The party was absent for nearly a year and a half, and though sure traces of Leichhardt were not found, much rich country and new watersheds were discovered. Under the auspices of the New South Wales Government, the search for Leichhardt was renewed in 1858, but again little success rewarded the efforts of the explorer. The Royal Geographical Society, however, showed its appreciation of his labours by conferring upon him the gold medal. In the following year he was appointed Surveyor-General of Queensland, and he afterwards held several posts of distinction under the Queensland Government. He was the author of several papers on Australian geology and geography.

THE editor of the Berlin *Post* has been kind enough to bring under our notice some flagrant instances of the publication in German newspapers, without acknowledgment, of translations of articles and other contributions which originally appeared in our columns. These translations have been published under the title of "Allgemeine wissenschaftliche Berichte," and the editor of the Berlin *Post* has supplied us with a list of no less than twenty cases in which articles have been taken from NATURE and translated into German without any indication of their source. The free use which has thus been made of contributions to our pages may doubtless be regarded as a flattering testimony to their scientific interest and precision; but at the same time, we must express regret that the morality of some writers on scientific subjects in Germany should have sunk so low that they can calmly render our contributions into their own language and offer the translations to newspapers as original descriptive matter. We are glad to know that this iniquitous practice has been discovered by the editor of the Berlin *Post*, and we trust that it will be exposed by the newspapers which have unknowingly printed translations of contributions to our pages.

AMONG the biological contents of the second part of the ninth volume of the *Bulletin International* issued at Prague by the Académie des Sciences de l'Empéreur François Joseph is an article by Mr. F. Brabenec on a new discovery of fossil plants in the Tertiary deposits of Holedeč, Bohemia. In addition to a new acacia, the author records remains of two species of the S. European aquatic genus Salvinia, one of which is very rare. In another article Dr. B. Němec discusses the influence of light on the position of the leaves in *Vaccinium myrtilus*, while in a third Mr. J. Smolák records the existence of multinuclear cells in certain euphorbias. The European representatives of the insect family Dictyopterygidæ form the subject of the one article, by Prof. F. Klapálek, relating to morphological zoology.

REGENERATION and development constitute the leading features of the second part of vol. lxxix. of the *Zeitschrift für wissenschaftliche Zoologie*, which contains three articles. The first of these subjects is discussed by Prof. J. Nusbaum, of Lemberg University, who takes as his text the polychæte annelids *Amphigene mediterranea* and *Nerine cirratulus*, and shows how almost every part of the organism may be reproduced. As regards development, Dr. E. v. Zeller discusses the vesiculæ seminales in newts, and Dr. E. Zander contributes an article on the male generative organs of the Microlepidoptera of the family Butalidæ. The latter communication has an interest not indicated in the title, since it discusses the statement that these insects depart from the normal type in possessing only nine (in place of ten) abdominal segments. According to the author, this is an error, due to the wrong orientation of preparations and the consequent mistaking of a true segment for part of the generative apparatus.

IN honour of the International Ornithological Congress, the current issue of *Bird Notes and News* forms a double number, of which the contents include a four-page supplement dealing with protective legislation for birds throughout the British Empire, and likewise an article on international bird-protection, in which attention is directed to the urgency of international agreement on the subject, more especially in regard to rare species, migratory birds,

and species persecuted for the sake of their plumage. Among other cases mentioned in the article on international bird-protection, special reference is made to the wholesale destruction of penguins in Macquarie Island, and perhaps elsewhere, for the sake of their oil, a destruction which if continued and extended can only result in the extermination of these remarkable and interesting birds. If certain current reports be true, not only is there need of the best efforts of the Bird Protection Society, but the Society for the Prevention of Cruelty to Animals has also a field for its operations, if its arm be long enough to reach the Antarctic.

THE amount of variation that was obtained in cultivating a five-rayed form of *Trifolium pratense* is the subject of a paper by Miss T. Tammes in part xi. of the *Botanische Zeitung*. The production of more than three rays may be regarded as the dominance of the variety, while the production of trifoliate leaves is a reversion to the original form. In the early stages, that is, on first order branches, the leaves generally showed more than three leaflets, but later the trifoliate character was almost constant.

THE avocado or alligator pear, *Persea gratissima*, is rapidly growing in favour with Americans as a salad fruit. On this account Mr. J. H. Rolfs has prepared an account of its cultivation in Florida, which forms Bulletin No. 61 of the Bureau of Plant Industry. Budding affords the most satisfactory method of propagation, as plants do not come true to seed. Two forms are cultivated, the West Indian and a smaller-fruited Mexican variety. The fruit, which only resembles a pear in shape, is eaten like an egg, without condiments or with salad accompaniments.

ALTHOUGH sandal-wood is an important source of revenue in the Indian States of Mysore and Coorg, the parasitic nature of the sandal-tree has been little studied. Mr. C. A. Barber, who originally pointed out that the sandal is a root parasite, producing haustoria, by which it absorbs nourishment from the roots of such host plants as Casuarina and Lantana, has published in the *Indian Forester* (April) an account of further investigations on the subject. The haustorial tissue penetrates the root along the line of the cambium, and thrusts aside the cortex of the host, while absorbent cells and tracheæ are formed to abstract and carry off the food solutions from the wood.

IN the *Engineering and Mining Journal* Mr. F. Danvers Power, professor of mining in the University of Sydney, publishes an important memoir on the Gympie Goldfield of Queensland. The district is of special geological interest in view of the enrichment of the gold-bearing quartz veins where they pass through four beds of black shale containing graphite. The deepest shaft in the district has attained a depth of 3130 feet.

WE have received from the Engineering Standards Committee three further reports, dealing respectively with structural steel for shipbuilding, with screw threads, and with pipe threads for iron or steel pipes and tubes. These standard specifications have been drawn up by influential committees composed of representatives of the Institutions of Civil Engineers, Mechanical Engineers and Naval Architects, the Iron and Steel Institute, and the Institution of Electrical Engineers, and will doubtless be generally adopted. In the case of screw threads, no departure from the Whitworth thread is recommended, and terms used by the British Association small screw gauge committee have, to a large extent, been adopted.

IN a recent paper on the determination of sulphuric acid in soils, attention was directed to the enormous loss of sulphuric anhydride due to the solubility of barium sulphate in ferric chloride solution. If such low results are obtained when determining the sulphur in the presence of small quantities of iron, what losses must be entailed where large amounts of iron are present, as in the case of iron ore? An experimental investigation of the subject has been made by Mr. J. Howard Graham, and the results are published in the *Journal of the Franklin Institute*. They show that barium sulphate is not soluble in ferric chloride to the extent mentioned, but rather that it acts restrainingly upon the act of solution of the barium sulphate in hydrochloric acid until too large quantities of the acid are present.

SINCE their discovery, the various constituents of steel have been the object of numerous researches: but the knowledge of the internal structure of steel has been to a great extent obscured by the acrimonious controversies that have been introduced into the discussion of this subject at meetings of the Iron and Steel Institute. An attempt to remove the existing confusion has been made by Dr. Glazebrook and Prof. H. Le Chatelier by suggesting the formation of an international committee to investigate the matter. The committee is composed as follows:—France: MM. Charpy, Pérot, and H. Le Chatelier; Great Britain: Mr. Hadfield (president of the Iron and Steel Institute), Prof. Arnold, Mr. Stead, F.R.S., and Dr. Glazebrook, F.R.S.; Germany: Prof. Martens; Russia: Mr. Kournakoff; Sweden: Messrs. Brinell and Gunnar Dillner; United States: Messrs. H. M. Howe and Sauveur. The scheme of investigation is published in the current issue of the *Bulletin de la Société d'Encouragement pour l'Industrie nationale*.

THE twenty-seventh report of the Deutsche Seewarte, Hamburg, for the year 1904, shows that the work of marine meteorology and weather prediction is being prosecuted with the usual vigour shown by this useful organisation, and that Admiral Herz is careful to maintain the high efficiency which it attained under the able direction of Dr. von Neumayer. At the end of the year 1904 the number of observers at sea amounted to no less than 837; they are encouraged in their work by the presentation of medals and diplomas, in special cases, in addition to free distribution of atlases and sailing directions. Eleven hundred pilot charts of the North Atlantic Ocean are published monthly, and a similar publication is contemplated for the Indian Ocean; and twelve hundred charts for the North Sea and Baltic are issued quarterly. These are in addition to the publication of larger general discussions at irregular intervals. In the department for weather telegraphy and storm warnings, it may be mentioned that the comprehensive daily weather report shows a considerable improvement by the insertion of kite observations on p. 1. Storm warning telegrams were issued on sixty days, the number of messages to hoist storm signals amounting to 2593. The report exhibits similar activity in other branches of the Seewarte.

THE report on the currents at the entrance of the Bay of Fundy and southern Nova Scotia for the year 1904 has recently been issued. The season from May to September was chiefly occupied by Mr. Bell Dawson, the surveyor in

charge of the work, in examining the currents at the entrance of the Bay of Fundy extending from Grand Manan Island to Cape Sable. These currents were found to be strong, steady, and deep, and therefore contrasted with those previously surveyed on the coasts of Newfoundland. A correct knowledge of the currents in the region surveyed is of great importance to navigation, as it includes waters that lie on the lines of ocean steamships running to St. John's, N.B., as well as of steamers from the United States ports which round the southern end of Nova Scotia on their way to Europe. It has been ascertained from the tide gauges which have been fixed during the survey and the tides recorded since 1902 that from Cape Sable westward the tides can be satisfactorily referred to St. John's, while eastward of Cape Sable they can be referred to Halifax. One noteworthy fact brought out by the survey is that the difference in range between spring tides which fall at perigee or apogee respectively is as great as the difference between mean springs and neaps, showing the dominating influence of the moon's distance in this region; and the variation in the strength of the current is found to follow the same law. Thus at St. John's the range at S.T., when the moon is at perigee, is 27·10 feet, and at apogee 20·35 feet, showing a difference of 6·75 feet. Mean spring range is 23·72 feet, and neaps range 17·43 feet, showing a difference of 6·29 feet. Also the diurnal inequality which is a dominant factor in parts of the Gulf of St. Lawrence is not very strongly marked in this region, although still quite appreciable. It was found that wind disturbance seldom affects the currents at a depth of more than ten fathoms, and that while along the centre line of the Bay of Fundy between the fifty fathoms' line on each side the ebb current runs only at the rate of $1\frac{1}{2}$ to $2\frac{1}{2}$ knots, nearer the shore about eight miles to the right or left the rate is nearly double, or from 3 to 4 knots. The report is accompanied by a map of the Bay of Fundy showing the direction and strength of the tidal currents.

AN index to the literature of indium, by Dr. P. E. Browning, has just been published by the Smithsonian Institution, and forms part of vol. xlvi. of the Smithsonian Miscellaneous Collections.

SOME remarkable finds of rare minerals have been made during the opening up of the noted gadolinite locality in Llano County, Texas; they are reported upon by Mr. W. E. Hidden in the June number of the *American Journal of Science*. The development of the mines was undertaken by the Nernst Lamp Co., of Pittsburg, Pa., and among the most notable discoveries were a double crystal of gadolinite weighing 73 lb., a mass of yttrialite weighing 18 lb., and a piece of pure allanite that weighed more than 300 lb. A single crystal of smoky quartz had a weight of 600 lb., and in a single year more than 1000 lb. of nearly pure gadolinite were extracted. Many of the minerals were radio-active, and deep work in the locality seems likely to bring to light new combinations of the rare earths and of uranium and thorium.

IN No. 4 of the *Bulletin International* of the Academy of Sciences of Cracow, M. T. Godlewski shows that it is possible to separate from actinium by a similar method to that used for isolating ThX from thorium an intensely radio-active substance to which the name actinium X is given. The residual actinium is nearly inactive, retaining only 5 per cent. of its original activity, but it recovers its activity with time according to an exponential curve; the activity of actinium X, on the other hand, decays according to an exponential curve complementary to the curve of recovery. As in the case of thorium, the emanation of actinium is shown to be due to a transformation of actinium X. A complete analogy thus appears to exist between the radio-activity of actinium and thorium. It is interesting, however, to note that actinium itself is probably inactive, whilst thorium free from thorium X has never been obtained with less than 25 per cent. of its original activity. Moreover, the β rays of actinium are completely distinct in character from the β rays emitted by other radio-active elements, inasmuch as they are completely homogeneous with regard to their absorption by solid bodies.

A PAPER by Prof. Theodore W. Richards, Lawrence J. Henderson, and George S. Forbes, which is published in the *Proceedings of the American Academy of Arts and Sciences* (vol. iv., No. 1), deals with the question of the elimination of accidental loss of heat in accurate calorimetry. It is shown that the lag of the thermometer behind the temperature of a slightly cooling or slightly warming environment causes an appreciable error in estimating the temperature of the environment; by a simple method this lag can be accurately determined and allowed for. A new method for obviating this and all other corrections for cooling is shown to consist in systematically altering the temperature of the environment at the same rate and to the same degree as that of the calorimeter proper; this may be effected by allowing a chemical action which liberates heat to take place outside the calorimeter at a graduated velocity. This method is shown in a series of experiments to give a more constant result than can be obtained by introducing a correction for cooling according to the method of either Régnault or Rumford. It is shown, moreover, to give essentially the same value as that afforded by the older methods when these are corrected for the lag of the thermometer.

IN studying the action of fluorine on some compounds of nitrogen, MM. Moissan and Lebeau found that whilst there was no reaction between fluorine and nitrogen peroxide (NATURE, June 22, p. 183) there was a vigorous reaction between fluorine and nitric oxide. In the current number of the *Comptes rendus* they give a further account of their work on this reaction, from the products of which they have succeeded in isolating a new compound of fluorine, nitrogen and oxygen, nitryl fluoride, NO_2F. The gaseous products of the reaction, cooled to the temperature of boiling oxygen, gave a white solid which on fractionation at a low temperature proved to consist of a mixture of fluorine and a new substance, condensable at $-80°$ C. By repeated distillation this latter was obtained in a pure state, and gave figures on analysis corresponding to the formula NO_2F. In the gaseous state this has a density of 2·24, the theoretical density being 2·26, a melting point of $-139°$ C. and a boiling point of $-63°·5$ C. Nitryl fluoride possesses very active chemical properties, combining at the ordinary temperature with boron, silicon, phosphorus, arsenic, antimony, and iodine. It is without action in the cold on hydrogen, sulphur, and carbon, but decomposes water, producing nitric and hydrofluoric acids, and reacts with a large number of organic compounds, giving nitro- and fluor-derivatives.

THERE will be an extra meeting of the Physical Society on Friday, June 30, at the Royal College of Science, South Kensington, when the following papers will be read:—the comparison of electric fields by means of an oscillating

electric needle: Mr. David Owen; (1) the magnetic rotatory dispersion of sodium vapour, (2) the fluorescence of sodium vapour: Prof. R. W. Wood. In addition to illustrating his papers by experiments, Prof. Wood proposes to show a number of other experiments.

At a meeting of the Faraday Society to be held on Monday next, July 3, the following papers will be read:—some notes on the rapid electrodeposition of copper: Sherard Cowper-Coles; the use of balanced electrodes: W. W. Haldane Gee; (1) electrolytic oxidation of hydrocarbons of the benzene series, part ii., ethyl benzene, cumene and cymene; (2) electrolytic analysis of antimony: H. D. Law and F. Mollwo Perkin; notes on heat insulation, particularly with regard to materials used in furnace construction: R. S. Hutton and J. R. Beard.

OUR ASTRONOMICAL COLUMN.

Astronomical Occurrences in July:—

July 4. 4h. Venus and Jupiter in conjunction, Venus 2° 30′ S.
,, 5. 11h. 34m. Minimum of Algol (β Persei).
,, 6. 1h. Venus at greatest elongation, 45° 44′ W.
,, 15. Venus. Illuminated portion of disc = 0·551; of Mars = 0·881.
,, 16. Uranus passes 1′ north of 1 Sagittarii (Mag. 5·3).
,, 23. Saturn. Outer major axis of outer ring = 43″·22; outer minor axis of outer ring = 6″·88.
,, 26. 11h. Conjunction of Jupiter with the Moon, Jupiter 4° 24′ N.
,, 27. 10h. 6m. Minimum of Algol (β Persei).
,, 27–31. Epoch of Aquarid meteoric shower (Radiant 339° − 11°).

New Observatory in Algeria.—The accompanying illustration of the Mustapha-Supérieur Observatory (Algeria) is reproduced from *La Nature* (No. 1671), wherein M. Lucien Libert describes in detail the situation and

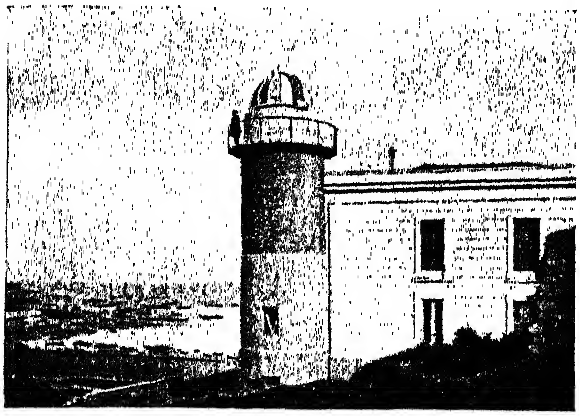

Fig. 1.—The Mustapha-Supérieur Observatory, Algeria.

equipment of the institution. This observatory was founded privately by M. Jouffray, and is situated to the east of Algiers, on a spur which forms the eastern extremity of the Sahel plateau, at an altitude of 172 metres (about 564 feet) above the sea-level. A special feature of this institution is its exclusive use of the decimal system. The equipment includes a Leroy "tropomètre," *i.e.* a centesimal chronometer, which divides the day into forty parts or "decagrades," and makes 100,000 beats per day instead of the 86,400 beats made by the ordinary chronometer. The elaborately fitted micrometer, which is used in connection with a Secretan equatorial of 135 mm. (5¼ inches) aperture and 187 cm. (6·1 feet) focal length, has its circle divided into 400 grades, the pitch of the screw being 1′ (centesimal), and M. Libert contends that the use of these scales effects an immense saving of time and labour. The electrical and mechanical arrangements for illuminating and controlling the instruments and the dome are described in detail, and appear to be as near perfection as possible. A complete meteorological equipment is also attached to the institution, and M. Libert pleads for the foundation of a similar observatory in southern Algeria, where the sky is but very rarely covered.

A Suspected Sudden Change on Jupiter.—At the meeting of the Royal Astronomical Society held on May 12, a note from Major Molesworth, R.E., was read in which he described a suspected instance of sudden change on Jupiter. Observing at Trincomalee, Ceylon, on December 17, 1903, he made a sketch of the neighbourhood surrounding the dark spot F 87, situated on the southern edge of the S. equatorial belt. This observation was made at 1h. 45·5m. G.M.T. At 2h. the observer suddenly noticed a minute white spot, bright enough to cause him some surprise at having omitted it from his previous observation, preceding and touching F 87. At 2h. 3m. this spot was so obvious that its existence could not have escaped the most casual observer, and later, at 2h. 5m., it had developed into a bright oblique rift only separated by a narrow streak from the spot F 83. This appearance lasted so long as the region remained readily observable. The region was again examined on December 20, but no trace of the outburst could be discerned. When first observed the bright spot was *preceding* F 87, but later the oblique rift appeared to enter the belt from a point immediately *following* that feature.

With a lengthy experience in observing Jupiter, Major Molesworth has never before noticed any such change in this region of the planet, but he is perfectly assured that the phenomenon was real. The observations were made under almost perfect conditions of seeing with a 12¾-inch Calver reflector fitted with a Steinheil monocentric eyepiece magnifying 270 times (*Monthly Notices*, May).

Brightness of Jupiter's Satellites.—In a recent note in these columns (May 18) attention was directed to the results obtained by Prof. Wendell from a photometric investigation of the relative brightnesses of Jupiter's satellites. He found that the invariable order of brightness of the satellites was iii., i., ii., iv., but, from a study of the photographic plates obtained at the Cape Observatory during 1891, 1903, and 1904, Prof. W. de Sitter finds that the order of magnitude was, invariably, iii., ii., i., iv., the interval ii.–i. being always of the same order as the intervals iii.–ii. and i.–iv. It thus appears that there must be a considerable difference between the visual and photographic magnitudes of these objects (*Astronomische Nachrichten*, No. 4026).

Elliptical Elements for the Orbit of Comet 1905 a.—Finding that the places derived from parabolic elements for the orbit of comet 1905 a did not agree sufficiently well with those observed, Prof. Banachiewicz calculated the following set of elements for an elliptical orbit from several observations made at various places on March 27, April 7, and April 27, and publishes the same in No. 4027 of the *Astronomische Nachrichten*:—

T = 1905 April 4·08096 (Berlin M.T.).

$$\left.\begin{aligned}\omega &= 358^\circ\ 12'\ 17''{\cdot}40\\ \Omega &= 157\ \ 27\ \ 41{\cdot}75\\ i &= 40\ \ 11\ \ 20{\cdot}76\end{aligned}\right\}1905{\cdot}0 \qquad \begin{aligned}\log q &= 0{\cdot}0470173\\ \log e &= 9\ 9856436\\ P &= 200{\cdot}62 \text{ years}\end{aligned}$$

The places derived from these elements were found to agree far more satisfactorily with the observed places.

According to a set of elements published by Herr A. Wedemayer in No. 4023 of the same journal, the period of this comet is about 279 years.

Recent Positions of Eros.—The following positions for Eros, on the dates named, have been derived from photographs taken by Mr. Manson at Arequipa with the Bruce telescope, apparently the first photographs of the asteroid to be obtained since its recent conjunction with the sun:—

1905	G.M.T. h. m.	Exposure. m.	α (1900) h. m. s.	δ (1900) ° ′
April 11	19 57	70	20 36 37	−25 4·5
12	20 41	134	20 38 34	−24 55·6
14	20 40	45	20 42 12	−24 39·1

(*Astronomische Nachrichten*, No. 4027).

TELESCOPIC WORK FOR OBSERVERS OF PLANETS.

THE possessors of telescopes now have an interesting variety of planetary objects for examination. These are Venus, Mars, Jupiter, Saturn, and Uranus.

Venus is visible, as a crescent, in the morning sky, increasing to half-moon shape in the second week of July, and arriving at her greatest elongation, west of the sun, on July 6, when her distance from that luminary will be 45° 44′. The conjunction of Venus and Jupiter will form an attractive spectacle on July 4.

Mars has now declined in diameter to 13″, but the principal markings are still very distinct, and some of the more delicate canals remain observable. After July the planet will have receded so far from the earth that further telescopic study of his physical lineaments cannot be pursued successfully.

Jupiter has just emerged into view as a morning star, rising about 2¼ hours before the sun. The most interesting point to be determined is the present position of the great red spot. The motion of this remarkable object has been curiously variable in recent years. Between October, 1904, and March, 1905, the rotation period corresponded very closely with that of system ii. of the ephemeris based on 9h. 55m. 40·63s., and the longitude remained constant at about 26°, so that the spot followed the passages of the zero meridian by 43 minutes. The exact position of the marking should be ascertained as early and as frequently as possible during the coming opposition, and the following are the probable times of a few transits during ensuing weeks:—

Date 1905	Approximate Transit Time h.	m.	Date 1905	Approximate Transit Time h.	m.
July 1	16	32	July 30	15	35
6	15	41	Aug. 4	14	45
11	14	51	6	16	23
13	16	29	9	13	53
18	15	39	11	15	32
23	14	48	13	17	10
25	16	27	21	13	49

The large dark spot seen in the south temperate zone of Jupiter in and since 1901, if still visible, will be in longitude 191° at the end of June, and will therefore follow the zero meridian by 5¼ hours and the great red spot by 4½ hours.

Saturn rises 5 hours before the sun. It is most important to learn whether there are any lingering signs of the extensive disturbance which affected the northern hemisphere in the summer and autumn of 1903. It is singular that, though a large number of observations of the spots were made and promptly reported in 1903, we have heard practically nothing of similar results in 1904. Yet the markings remained visible, if much less conspicuously, in 1904.

Uranus was in opposition to the sun on June 23, and is therefore easily discernible at the present time, though his southern declination is 23¾° An excellent opportunity will be afforded of identifying this planet during the third week in July, when he passes about 1 minute of arc north of the star 1 Sagittarii (mag. 5·3).

Added June 25.—The great red spot on Jupiter was seen by the writer at Bristol, and estimated central on June 24 15h. 43m. Its longitude was therefore 25°·1, and this sufficiently shows that its motion has exhibited no further change during the last three months.

Saturn was also carefully examined on the same morning, but no conspicuous spots were seen in a 12½-inch reflector by Calver, power 235. The observation of Jupiter was obtained with a 10-inch reflector by With-Browning, power 205. W. F. DENNING.

THE ROYAL SOCIETY CONVERSAZIONE.

THE second, or ladies', conversazione of the Royal Society was held in the rooms of the society at Burlington House on Friday last, June 23, and was attended by a large and distinguished company. As on former occasions, many objects of scientific interest were exhibited, but most of them were shown at the earlier conversazione on May 17, and have already been described in these columns (May 25, p. 90). It is therefore only necessary now to refer to additional demonstrations and exhibits.

In the course of the evening there were demonstrations, with lantern illustrations, on recent work in mimicry and protective resemblance, by Prof. E. B. Poulton, F.R.S., and on the three-colour photographic process, by Sir W. de W. Abney, K.C.B., F.R.S. The photographs in colour that were shown were prints from three negatives taken of each subject. Each of the three negatives was taken through an appropriate coloured medium, and the three transparent prints were projected on a screen with appropriate coloured screens behind them, giving the colours of nature. The process and apparatus employed were based on those of Mr. Ives.

Brief descriptions of the new exhibits are given in the subjoined abstract of the official catalogue.

The metal sodium, prepared so as to show its true colour and lustre: Mr. G. T. Beilby. The specimen was prepared by Dr. Thomas Ewan by melting the metal *in vacuo* in one vessel and running the clean, bright part of the liquid into another communicating vessel which had been freed from condensed air or moisture by heating during exhaustion. After solidification of a crystalline crust on the glass, the surplus liquid was run back into the first vessel and the specimen globe was sealed off.—(1) Pictures produced in the dark on a photographic plate by different woods; (2) ordinary photographs of the same woods; (3) the woods used in the experiments: Dr. W. J. Russell, F.R.S. The pictures taken in the dark were obtained on an ordinary rapid photographic plate, the wood being in contact with the plate from one to eighteen hours at a temperature of 55° C. The pictures were developed in the same way as if they had been produced by light.

The entoptoscope, a new form of ophthalmoscope: Prof. W. F. Barrett, F.R.S. The instrument was devised by the exhibitor for the self-examination of the eye by means of pinhole vision—entoptic diagnosis (Listing). When an illuminated fine pinhole in a sheet of metal is held near the eye, sharp shadows of any opaque or semi-opaque object in the path of the rays within the eyeball are thrown on the retina. By this means the growth of cataract from its earliest stages can be traced. By using two closely adjacent pinholes in the revolving diaphragm, and the transparent scale in the eye-piece, the exact magnitude and distance from the retina of the opacity can be determined.—The Ettles-Curties ophthalmometer and ophthalmic microscope: Mr. C. Baker. The ophthalmometer is an instrument for measuring the radius of curvature of the cornea, and consequently of ascertaining the dioptric value of the refracting medium bounded by that curvature. The instrument consists of an attachment by which the patient's head is steadied, and a telescope with Wollaston prism for observing the images of the "mires." The latter are carried on an arc graduated in terms of dioptres and radius of curvature, and prismatic steel bars provide a steady movement by rack and pinion to the adjustable parts. The whole is mounted on a telescopic floor standard which contains a plunger actuated by a spiral spring; by slight pressure this can be pushed down to the level of the patient's eye and clamped. The ophthalmometer can be detached and a microscope provided with electric illumination substituted.

Tantalum, and tantalum electric lamps: Messrs. Siemens Bros. and Co., Ltd. The exhibit comprised (1) specimens of the metal tantalum in the form of small blocks of more or less purity, also sheets and metallic powder, and specimens of wire of various thicknesses; (2) a series of tantalum glow lamps, requiring 110 volts and 0·34 ampere to give a light of 25 N.C. (1½ watts per candle-power).—The "Osmi" incandescent lamp: the General Electric Company. The lamp in appearance is similar to the ordinary electric bulb, but in place of carbon the filament is made from the rare metal osmium, which, when in a state of incandescence, glows with extreme brilliancy. The advantages claimed are:—high fusing point, white light, higher electrical efficiency, longer life, saving of current, less heat. The blackening of bulbs is inappreciable. The consumption of current with ordinary carbon filament lamp is 3·5 to 4 watts per candle-power. Consumption of current

with Osmi lamp, 1·5 watts per candle-power.—Fery radiation pyrometer: the Cambridge Scientific Instrument Company. By means of a concave mirror the image of a hot body or of the inspection hole in a furnace wall is focused upon a copper-constantan thermo-couple connected to a direct-reading galvanometer on the centigrade scale. The instrument was shown working, being sighted upon a disc of hot iron within an electrical resistance furnace.

Drawings made from combined photographs of the solar corona in 1898, 1900, and 1901: the Astronomer Royal. In 1901 a change in the corona on the west side appears to have taken place in the interval (thirty-seven minutes) between two photographs taken at different stations. The drawings were by Mr. W. H. Wesley.—(1) Photographs, maps, curves, and diagrams, in connection with the more recent researches on the astronomical significance of British stone circles. (2) Contact positives showing some of the results taken with the Solar Physics Observatory spectroheliograph. Also four enlarged pictures showing disc and disc-and-limb photographs, and a photograph of the instrument itself. (3) A series of curves to illustrate the relationship between the flow of the river Thames and pressure and rainfall changes in Great Britain. The close association between British pressure and the barometric see-saw between the Indian and South American areas was also indicated: Sir Norman Lockyer, K.C.B., F.R.S.—A new sundial that tells standard time, designed by Prof. Albert Crehore: Sir W. H. Preece, K.C.B., F.R.S. The gnomon of the common form of dial is abandoned, and the shadow of a small bead fixed on a wire is cast on the interior of a true cylindrical surface, upon which figure-of-eight curves are drawn marking standard noon for each day of the year. The cylindrical surface is inclined so that its axis, upon which the bead is fixed, is parallel to that of the earth. It thus represents the latitude of the place. The shadow of the bead travels across the cylindrical surface parallel to, or on, one of the circles drawn thereon. These circles represent days of the month. Each hour described in the circle is always of the same length, and a scale of minutes engraved on the cylinder enables true mean time to be read off directly to a few seconds.

Photographs illustrating the annual growth of a deer's antlers: Mr. H. Irving. The deer photographed was a wapiti, full grown. The first photograph showed the deer on the second day after the antlers were cast. Succeeding photographs were taken at fortnightly intervals covering four months' growth. The antlers were also shown with the velvet in strips, and finally clean and hard. The antlers of the previous year were shown for comparison.—Mendelian heredity in rabbits: Mr. C. C. Hurst. A pure-bred "Belgian hare," mated with a pure-bred white Angora, gave all wild-grey rabbits. These, bred together, gave the ten types exhibited, in which appear all the possible combinations of four pairs of coat characters, viz. short and angora, coloured and white, grey and black, self-coloured and Dutch-marked. The breeding behaviour of these types demonstrates clearly the Mendelian principles of dominance, segregation, and gametic purity. Dominant characters are short, coloured, and grey coat. Recessive characters are Angora, white and black coat. The black and Dutch-marked characters were introduced by the white Angora.—(1) Individual, local, and orthogenetic variation in Mexican lizards of the genus Cnemidophorus; (2) three specimens of *Chirotes canaliculatus* from Rio Balsas, South Mexico: Dr. H. Gadow, F.R.S. The former exhibit included:—*Cnemidophorus deppei*, showing orthogenetic variation in the number of white dorsal stripes from 7 to 11. Local variation from completely white to black underparts; from lateral white spots to double red bands. *C. striatus* and *C. guttatus*. Leading from a sharply striped pattern to the dull-coloured and completely spotted form which is characteristic of the eastern forest region. *C. gularis, C. mexicanus, C. bocourti*, and other closely allied forms, varying in size, colour, pattern, and scales.—(1) Demonstration illustrating the life-history of wood-boring wasps (Crabronidæ); (2) photographs from life of transformations of the brimstone butterfly (*Gonepteryx rhamni*): Mr. Fred Enock. The Crabronidæ, or wood-boring wasps, excavate (with their mandibles) deep burrows in decaying tree trunks, palings, &c., their work being carried on day and night until a sufficient depth has been reached. The female wasp then flies off in search of prey to stock her cells with food for the larvæ. A number of species inhabit Great Britain. Each selects its prey from certain insects, and invariably keeps to the species so selected. The intelligence exhibited by the wasp when "collecting" is marvellous, a momentary glance as the insects dart past being sufficient to identify the right one.—The membranous labyrinth of man and some animals: Dr. Albert A. Gray. The exhibit represented the membranous labyrinths of man, illustrating normal and pathological conditions; the membranous labyrinth of the seal showing otoliths; the membranous labyrinths of the mouse, the rat, the rabbit, the sheep, the cat, the lemur, the duck, the hen. The brain of the haddock, with the otoliths in their natural position.

(1) Restoration of a British Jurassic theropodous Dinosaur of the genus Streptospondylus from the Oxford Clay, Oxford; (2) British armoured Dinosaur: Dr. Francis Baron Nopcsa. The bipedal dinosaurian reptile shown in the first exhibit is the most complete representative of the genus discovered in this country. The type exists in the Paris Museum, but is very imperfect. The specimen from which Baron Nopcsa's restoration is prepared is in the private museum of Mr. J. Parker, of Oxford, and is about to be described by the exhibitor. The restoration was executed under the direction of Dr. Francis Baron Nopcsa by Miss Alice B. Woodward. Diagram reconstruction of skeleton and bony dermal armour of *Polacanthus Foxi*, Hulke, from the Wealden of the Isle of Wight. Reconstructed by Dr. Francis Baron Nopcsa, under the direction of Dr. Arthur Smith Woodward, F.R.S., and set up in the geological department of the British Museum.

Ethnological specimens from southern Mexico: Mrs. Gadow. The specimens comprised embroidered leather dancing dress; decorated cotton huipiles, from eastern Oaxaca and South Guerrero; white cotton shifts, embroidered with beads, South Guerrero; dancing masks, from Coacoyulichan, South Guerrero; clay and stone idols and sacred vessels; clay whistles, kitchen utensils, ancient and modern; copper, flint, and stone implements; and duck-shaped water vessels.

Photographs of the White Nile and its tributaries, taken by the Survey Department of Egypt, 1903: Captain H. G. Lyons. (1) Bahr el Jebel. The stations of Gondokoro, Lado, Mongalla, and Kiro; in this part the valley floor is about 2–4 feet above low-water level; at Ghaba Shambe and Hellet Nuer it is only 1–2 feet above it, and in this reach the greatest development of the marshes occurs, as well as the blocks of vegetation (Sudd). (2) Bahr el Ghazal and Bahr el Zaraf, showing their flat flood plains. (3) Sobat River in flood near its junction with the White Nile. (4) The White Nile. (5) Shilluk Negroes of the White Nile and Sobat.—Photographic views illustrative of the scenery of Tibet: the Royal Geographical Society.

SUBMARINE NAVIGATION.[1]

SUBMARINE navigation has engaged the attention of inventors and attracted general interest for a very long period. Its practical application to purposes of war was made about 130 years ago. Under the conditions which prevailed a century ago in regard to materials of construction, propelling apparatus, and explosives, the construction of submarines necessarily proceeded on a limited scale, and the type practically died out of use, almost at its birth. Enough had been done, however, to demonstrate its practicability and to make it a favourite field of investigation for inventors, some of whom contemplated wide extensions of submarine navigation. Every naval war gave fresh incentive to these proposals, and led to the construction of experimental vessels. This was the case during the Crimean War, when the Admiralty had a submarine vessel secretly built and tried by a special committee, on which, amongst others, Mr. Scott-Russell and Sir Charles Fox served. Again, during the Civil War in America, the Confederates constructed a submarine vessel, and used it against the blockading squadron off Charlestown. After several abortive attempts, and a considerable

[1] Abstract of a discourse delivered at the Royal Institution on Friday, June 9, by Sir William H. White, K.C.B., F.R.S.

loss of life, they succeeded in destroying the Federal *Housatonic*, but their submarine with all its crew perished in the enterprise.

It is impossible to give even a summarised statement of other efforts made in this direction from 1860 onwards to 1880; but one cannot leave unnoticed the work done in the United States by Mr. Holland, who devoted himself for a quarter of a century to continuous experiment on submarines, and eventually achieved success. The Holland type was first adopted by the United States Navy, and was subsequently accepted by the British Admiralty as the point of departure for our subsequent construction of submarines. In France, also, successive designs for submarines were prepared by competent naval architects, and a few vessels were built and tried. The *Plongeur*, of 1860, was a submarine of large size, considerable cost, and well considered design; but her limited radius of action and comparatively low speed left her for many years without a successor on the French Navy List.

The modern development of submarines for war purposes is chiefly due to French initiative. During the earlier stages of this development progress was extremely slow. The *Gymnote* was ordered in 1886 and the *Gustave Zédé* in 1888, and her trials continued over nearly eight years, large sums of money being spent thereon. In 1896 competitive designs for submarines were invited, but no great activity was displayed in this department of construction until the Fashoda incident two years later. Since that time remarkable developments have been made in France, considerable numbers of submarines have been laid down, rival types have been constructed, and many designers have been engaged in the work. Up to the present time about seventy submarines and submersibles have been ordered; in July, 1904, the total number of completed vessels was twenty-eight, and at the end of 1907 it is estimated that France will possess sixty completed submarines, with a total displacement of nearly 13,600 tons. The first French submarine of modern type, the *Gymnote*, was 56 feet long and of 30 tons displacement. The latest types are nearly 150 feet long and of 420 tons displacement. The cost of a French submarine designed in 1898 was about 26,000*l*. The estimated cost of the latest and largest vessels is about 70,000*l*.

Two years elapsed after the date when the French resolutely undertook the construction of submarines before the British Admiralty ordered five vessels of the Holland type from Messrs. Vickers, Sons and Maxim, who had acquired the concession for the use of the Holland Company's patents. These first vessels in essentials were repetitions of the type which had been tried and officially approved by the authorities of the United States Navy. It was agreed that all improvements made by the Holland Company should be at the service of the British Admiralty through the English *concessionnaires*. Our first five submarines are 63 feet in length, 120 tons in displacement, with gasolene engines of 160 horse-power for surface propulsion, giving a speed of 8 to 9 knots. The electric motors for submerged propulsion are estimated to give a speed of about 7 knots. The contract price for each vessel in the United States was about 34,000*l*., and that is about the price paid for our earliest vessels. The latest type of which particulars are available is said to be about 150 feet in length, 300 tons in displacement, and with gasolene engines of 850 horse-power for surface propulsion, giving a surface speed of 13 knots and a radius of action of 500 miles. The under-water speed is 9 knots, and the radius of action when submerged about 90 miles.

In French official classification a distinction is made between submarines and submersibles, and this terminology has been the cause of some confusion. Both classes are capable of diving when required, and both can make passages at the surface. In this surface condition a considerable portion of the vessel lies above the water-surface and constitutes what is technically called a "reserve of buoyancy." In the submersible this reserve of buoyancy and the accompanying freeboard are greater than in the submarine type, and in this respect lies the chief difference between the two types. The submersible has higher freeboard and greater reserve of buoyancy, which secure better sea-going qualities and greater habitability. The deck or platform is situated higher above water, and to it the crew can find access in ordinary weather when making passages, and obtain exercise and fresh air. Recent exhaustive trials in France are reported to have established the great superiority of the submersible type when the service contemplated may involve sea passages of considerable length. The French policy, as recently announced, contemplates the construction of submersibles of about 400 tons displacement for such extended services, and proposes to restrict the use of submarines to coast and harbour defence, for which vessels of about 100 tons displacement are to be employed. All recent British submarines would be ranked as submersibles according to the French classification, and it is satisfactory to know, as the result of French experiments, that our policy of construction proves to have distinct advantages.

In addition to these two types of diving or submarine vessels, the French are once more discussing plans which have been repeatedly put forward and practically applied by M. Goubet, namely, the construction of small portable submarine vessels which could be lifted on board large ships and transported to any desired scene of operations. In the Royal Navy, for many years past, it has been the practice similarly to lift and carry second-class torpedo or vedette boats about 20 tons in weight. Lifting appliances for dealing with these heavy boats have been designed and fitted in all our large cruisers and in battleships, and a few ships have been built as "boat-carriers." The first of these special dépôt ships in the Royal Navy was the *Vulcan*, ordered in 1887-8, the design being in essentials that prepared by the lecturer at Elswick in 1883. The French have also built a special vessel named the *Foudre*, which has been adapted for transporting small submarines to Saigon, and performed the service without difficulty. Whether this development of small portable submarines will take effect or not remains at present an open question, but there will be no mechanical difficulty either in the production of the vessels themselves or in the means for lifting and carrying them.

Progress in mechanical engineering and in metallurgy has been great since Bushnell constructed and used his first submarine in 1776, during the war between the United States and this country. These advances have made it possible to increase the dimensions, speed, and radius of action of submarines; their offensive powers have been enlarged by the use of locomotive torpedoes, and superior optical arrangements have been devised for discovering the position of an enemy while they themselves remain submerged. But it cannot be claimed that any new principle of design has been discovered or applied. From descriptions left on record by Bushnell, and still extant, it is certain that he appreciated, and provided for, the governing conditions of the design in regard to buoyancy, stability, and control of the depth reached by submarines. Indeed, Bushnell showed the way to his successors in nearly all these particulars, and—although alternative methods of fulfilling essential conditions have been introduced and practically tested—in the end Bushnell's plans have in substance been found the best. The laws which govern the flotation of submarines are, of course, identical with those applying to other floating bodies. When they are at rest and in equilibrium they must *displace* a weight of water equal to their own total weight. At the surface they float at a minimum draught, and possess in this "awash" condition a sufficient freeboard and reserve of buoyancy to fit them for propulsion. When submarines are being prepared for "diving" water is admitted to special tanks, and the additional weight increases immersion, and correspondingly reduces reserve of buoyancy. In some small submarines comparative success has been attained in reaching and maintaining any desired depth below the surface simply by the admission of the amount of water required to secure a perfect balance between the weight of the vessel and all she contains, and the weight of water which would fill the cavity occupied by the submarine when submerged. For all practical purposes and within the depths reached by submarines on service water may be regarded as *incompressible*; the submarine should, therefore, rest in equilibrium at any depth if her total weight is exactly balanced by the weight of

water displaced. If the weight of the vessel exceeds by ever so small an amount the weight of water displaced, that excess constitutes an accelerating force tending to sink the vessel deeper. On the contrary, if the weight of water displaced exceeds by ever so small an amount the total weight of the vessel, a vertical force is produced tending to restore her to the surface. In these circumstances, it is obvious that if the admission or expulsion of water from internal tanks (or the extrusion or withdrawal of cylindrical plungers for the purpose of varying the displacement) were the only means of controlling vertical movement, it would be exceedingly difficult to reach or to maintain any desired depth. This difficulty was anticipated on theoretical grounds, and has been verified on service—in some cases with considerable risks to the experimentalists—the submarines having reached the bottom before the vertical motion could be checked. It has consequently become the rule for all submarines to be left with a small reserve of buoyancy when brought into the diving condition. Submergence is then effected by the action of horizontal rudders controlled by operators within the vessels. Under these conditions, submergence only continues so long as onward motion is maintained, since there is no effective pressure on the rudders when the vessel is at rest. The smallest reserve of buoyancy should always bring a submarine to the surface if her onward motion ceases, and, as a matter of fact, in the diving condition that reserve is extremely small, amounting to only 300 lb. (equivalent to 30 gallons of water) in vessels of 120 tons total weight. This is, obviously, a narrow margin of safety, and necessitates careful and skilled management on the part of those in charge of submarines. A small change in the density of the water, such as occurs in an estuary or in the lower reaches of a great river, would speedily obliterate the reserve of buoyancy and cause the vessel to sink if water was not expelled from the tanks. Moreover, variations in weight of the submarine (due to the consumption of fuel, the discharge of torpedoes or other causes) must sensibly affect the reserve of buoyancy, and arrangements must be made to compensate for these variations by admitting equal weights of water in positions that will maintain the "trim" of the vessel. Additional safeguards against foundering have been provided in some submarines by fitting detachable ballast. The more common plan is to make arrangements for rapidly expelling water from the tanks either by means of pumps or by the use of compressed air. In modern submarines, with locomotive torpedoes, compressed air is, of course, a necessity, and can be readily applied in the manner described if it is desired to increase their buoyancy.

The conditions of stability of submarines when diving are also special. At the surface, owing to their singular form, the longitudinal stability is usually much less than that of ordinary ships. When submerged, their stability is the *same in all directions*, and it is essential that the centre of gravity shall be kept below the centre of buoyancy. This involves no difficulty, because water-ballast tanks can be readily built in the lower portions of the vessels. Small stability in the longitudinal sense, however, necessitates great care in the maintenance of trim, and in the avoidance of serious movements of weights within the vessels. Moreover, when a vessel is diving under the action of her longitudinal rudders, she is extremely sensitive to changes of trim, and great skill is required on the part of operators in charge of working the rudders. As the under-water speed is increased, the pressure on the rudders for a given angle increases as the *square* of the velocity, and sensitiveness to change of trim becomes greater. This fact makes the adoption of higher under-water speed a matter requiring very serious consideration. Some authorities, who have given great attention to the construction of submarines, have been opposed to the adoption of high speeds under water, because of the danger that vessels when diving quickly may reach much greater depths than are desirable. Causes of disturbance which might be of small importance when the under-water speed is moderate may have a greatly exaggerated effect when higher speeds are reached. Cases are on record where modern submarines in the hands of skilled crews have accidentally reached the bottom in great depths of water, and have had no easy task to regain the surface. For these reasons, it is probable that while speeds at the surface will be increased, under-water speeds will not grow correspondingly. Indeed, the tactics of submarines hardly appear to require high speed under water, seeing that it is an important element in successful attack to make the final dive at a moderate distance from the enemy. It is authoritatively stated that in our submarines complete control of vertical movements has been secured by means of skilled operators, and that a constant but moderate depth below the surface can be maintained. Proposals have been made and successfully applied to small submarines for automatically regulating the depth of submergence by apparatus similar to that used in locomotive torpedoes. For the larger submarines now used such automatic apparatus does not find favour, and better results are obtained with trained men.

The possibility of descending to considerable depths has to be kept in view when deciding on the form and structural arrangements of submarines, which may be subjected accidentally to very great external pressure. It is absolutely necessary to success that, under the highest pressure likely to be endured, there shall be rigidity of form, as local collapse of even a very limited amount might be accompanied by a diminution in displacement that would exceed the reserve of buoyancy. This condition is not difficult of fulfilment, and the approximately circular form usually adopted for the cross-sections of submarines favours their resistance to external pressure.

Under former conditions, there was difficulty in remaining long under water without serious inconvenience from the impurity of the air. Now, by suitable arrangements and chemical appliances, a supply of pure air can be obtained for considerable periods, sufficient, indeed, for any operations likely to be undertaken.

The use of gasolene engines for surface propulsion has many advantages. It favours increase in speed and radius of action, and enables submarines to be more independent and self-supporting. Storage batteries can be re-charged, air compressed and other auxiliary services performed independently of any "mother" ship. At the same time, it is desirable to give to each group of submarines a supporting ship, serving as a base and store depôt, and this has been arranged in this country as well as in France. With gasolene engines, care must be taken to secure thorough ventilation and to avoid the formation of explosive mixtures of gas and air, otherwise accidents must follow.

Little information is available as regards the success of "periscopes" and other optical instruments which have been devised for the purpose of enabling those in command of submarines to obtain information as to their surroundings when submerged. In this department, secrecy is obviously desirable, and no one can complain of official reticence. From published accounts of experimental working abroad as well as in this country, it would appear that considerable success has been obtained with these optical instruments in comparatively smooth water. It is also asserted that when the lenses are subjected to thorough washing by wave-water, they remain efficient. On the other hand, the moderate height of the lenses above water must expose them to the danger of being wetted by spray even in a very moderate sea, and experience in torpedo-boats and destroyers places it beyond doubt that the resultant conditions must greatly interfere with efficient vision. In heavier seas, the comparatively small height of the lenses above water must often impose more serious limitations in the use of the periscopes and similar instruments. Improvements are certain to be made as the result of experience with these optical appliances, and we may be sure that in their use officers and men of the Royal Navy will be as expert as any of their rivals. But when all that is possible has been done, it must remain true that increase in offensive power and in immunity from attack obtained by submergence will be accompanied by unavoidable limitations as well as by special risks resulting from the sacrifice of buoyancy and the great reduction in longitudinal stability which are unavoidable when diving. These considerations have led many persons to favour the construction of so-called *surface-boats* rather than submarines. They would resemble submersibles in many respects, but the power of diving would be surrendered, although they would be so constructed that by admitting

water by special tanks they could be deeply immersed and show only a small target above the surface when making an attack. There would be no necessity in such surface vessels to use electric motors and storage batteries, since internal combustion engines could be used in all circumstances. Hence it would be possible without increase of size to construct vessels of greater speed and radius of action, and to simplify designs in other important features. It is not possible to predict whether this suggestion to adopt surface-boats rather than submersibles will have a practical result; but it is unquestionable that improvements in or alternatives to internal combustion engines will favour the increase of power in relation to weight, and so will tend to the production of vessels of higher speed.

Submarines and airships have certain points of resemblance, and proposals have been made repeatedly to associate the two types, or to use airships as a means of protection from submarine attacks. One French inventor seriously suggested that a captive balloon attached to a submarine should be the post of observation from which information should be telephoned to the submarine as to the position of an enemy. He evidently had little trust in periscopes, and overlooked the dangers to which the observers in the car of the balloon would be exposed from an enemy's gun-fire. Quite recently a proposal has been made by M. Santos Dumont to use airships as a defence against submarines, his idea being that a dirigible airship of large dimensions and moving at a considerable height above the surface of the sea could discover the whereabouts of a submarine, even at some depth below the surface, and could effect its destruction by dropping high explosive charges upon the helpless vessel. Here again, the inventor, in his eagerness to do mischief, has not appreciated adequately the risks which the airship would run if employed in the manner proposed, as submarines are not likely to be used without supporting vessels. Hitherto, submarines themselves have been armed only with torpedoes, but it has been proposed recently to add guns, and this can be done, if desired, in vessels possessing relatively large freeboard. No doubt if gun armaments are introduced, the tendency will be further to increase dimensions and cost, and the decision will be governed by the consideration of the gain in fighting power as compared with increased cost. As matters stand, submarines are practically helpless at the surface when attacked by small swift vessels, and it is natural that advocates of the type should desire to remedy this condition. Surface boats, if built, will undoubtedly carry guns as well as torpedoes, and in them the gun fittings would be permanent, whereas in submarines certain portions of the armament would have to be removed when vessels were prepared for diving.

Apart from the use of submarine vessels for purposes of war, their adoption as a means of navigation has found favour in many quarters. Jules Verne, in his "Twenty Thousand Leagues Under the Sea," has drawn an attractive picture of what may be possible in this direction, and others have favoured the idea of combining the supposed advantages of obtaining buoyancy from bodies floating at some depth below the surface with an airy promenade carried high above water. Not many years ago an eminent naval architect drew a picture of what might be accomplished by utilising what he described as the "untroubled water below" in association with the freedom and pure air obtainable on a platform carried high above the waves. These suggestions, however, are not in accord with the accepted theory of wave-motion, since they take no note of the great depths to which the disturbance due to wave-motion penetrates the ocean. The problems of stability, incidental to such plans, are also of a character not easily dealt with, and consequently there is but a remote prospect of the use of these singular combinations of submarine and aërial superstructures. There is little likelihood of the displacement of ocean steamships at an early date by either navigable airships or submarines, and the dreams of Jules Verne or Santos Dumont will not be realised until much further advance has been made in the design and construction of the vessels they contemplate.

THE INSTITUTION OF MECHANICAL ENGINEERS.

THE summer meeting of the Institution of Mechanical Engineers was held last week in Belgium. The opening proceedings took place in the city of Liége, the president, Mr. E. P. Martin, occupying the chair at the preliminary sitting. Six papers were down for reading and discussion, the mornings of June 20 and June 21 being devoted to their consideration. The following is a list of the papers:—Superheaters applied to locomotives on the Belgian State railways, by M. J. B. Flamme; the growth of large gas-engines on the Continent, by M. Rodolphe Mathot; ferro-concrete, and some of its most characteristic applications in Belgium, by M. Ed. Noaillon; electric winding machines, by M. Paul Habets; strength of columns, by Prof. W. E. Lilly; an investigation to determine the effects of steam-jacketing upon the efficiency of a horizontal compound steam engine, by Mr. A. L. Mellanby.

The first paper taken was the contribution by M. Flamme on superheating for locomotives. The author first dealt with the Schmidt superheater for simple expansion locomotives as applied on the Belgian State railways. Arrangements were made for superheating the steam, in order further to increase the power of the engines. As a result of experiments made, extending over some months, it was recognised that the utilisation of steam slightly superheated did not offer any appreciable economy of fuel or increase of power. On the other hand, with the Schmidt apparatus, when the steam was superheated from 570° F. to 662° F., favourable results were obtained. Two engines were tried, one using superheated steam and the other saturated steam. The saving in favour of the superheated steam locomotive amounted to 12·5 per cent. for fuel and 16·5 per cent. for water. Moreover, the speed reached showed an average increase of 9·5 per cent., all conditions being exactly the same. In regard to maintenance, the superheated steam locomotive type did not require special attention during its one and a half years' service. These favourable results led to the Belgian State railways venturing on the application of superheat to locomotives on a larger scale. With this in view, twenty-five locomotives, comprising five different types, all provided with the Schmidt superheater, were, at the time of the reading of the paper, actually in course of construction, or were about to be put to work. The Belgian State railway authorities had decided to persevere in their experiments in combining superheating of steam with compounding of the engine. The results obtained will be of very great interest. It was desirable to find whether it was more economical to divide the superheater into two parts in such a manner as to raise the temperature at the entrance to both high-pressure and low-pressure cylinders. The Cockerill Co., of Seraing, had completed a superheater which would enable this question to be settled.

The discussion on this paper was opened by Mr. Robinson, of Messrs. Sharp, Stewart, and Co., who stated that the Schmidt superheater had been tried on the Canadian Pacific Railway, and had been found to answer, whilst on the Cape railways the results had not been so satisfactory. He attributed the latter effect to the fact that the superheating tubes were placed at the lower part of the barrel of the boiler, instead of at the upper part as they should have been. Mr. Mark H. Robinson and the president also spoke.

The next paper taken was that of Mr. Paul Habets on electric winding machines. This was a long and somewhat abstruse paper, illustrated by many diagrams, and containing a large number of formulæ. It was read in brief abstract by the secretary of the institution. The author gave a dynamic investigation of haulage, dealing with the questions of resistance, statical moments, inertia of suspended loads, inertia of rope-roll, the head gear and winding gears of motors, and other elements of design. Formulæ were given for moments of the accelerating forces and power and expenditure of energy. Details of construction of motors were discussed, and some special devices explained. As a practical conclusion, the author stated that it might be safely concluded from trials of which particulars were given that the electric haulage machine,

even if it were not more economical than the best steam-driven machines, was certainly not more expensive. The greater facility and safety with which electricity can be used, the smoothness with which it works, and its much greater flexibility, would often make it preferable to the use of steam, even in a case where transmission of energy was not required; there could be no hesitation in the choice between the two systems when the power had to be transmitted from a distance, or where the production of energy could be centralised at one power station.

M. Ed. Noaillon's paper on ferro-concrete was next read. Ferro-concrete constructions, as is well known, consist of a mass in which iron or steel reinforcement is bedded. The author stated that round bars were generally used, as they facilitated the escape of air and the proper ramming of the concrete; there were also no sharp angles which would cut the concrete. On the other hand, the round section gave the lowest coefficient of adhesion for a given cross-section of metal. The following rules governing the construction had been prepared by Prof. Rabut:—(1) No connection should be made of iron to iron, as the concrete itself holds the parts together in the most economical manner. (2) At least two distinct systems of reinforcement should be used, one to take up the tensile stress and the other to take up the shearing stresses in the concrete; when necessary a third system should be used to take up the compressive stresses. (3) The reinforcement should be so arranged that the separate members may be stressed in the direction of their length, so that the stresses produced between the iron and the concrete should be tangential, and not normal to the axis of the members of the reinforcement. (4) Homogeneity of the structure should be taken advantage of by prolonging the iron parts of one portion of the structure into the thickness of the concrete of the adjoining portion. Other points were also given.

Methods of construction were described and illustrated. Some examples of reinforced concrete were given in the paper, the handsome dome of the new Central Railway Station at Antwerp being a prominent instance. This dome is a fine piece of architecture, but was designed first of all for an ordinary masonry structure, a fact which made it somewhat difficult for the architects to adapt it for ferro-concrete. The entire structure is 1800 tons in weight, and rests wholly upon the columns at the angles of the glass lights; these columns are Y-shaped in cross-section. The external shell has a uniform thickness of 3·15 inches, and is relieved by six moulded ribs following the meridian lines. The Renommée Hall at Liége was the next example of this kind of construction. It was designed expressly for the use of this material. The principal hall is covered by three cupolas, each 55 feet in diameter, placed at a height of about 50 feet above the level of the ground. Each cupola forms part of a sphere, which continues in haunches, pierced with lights, and descending to the corners of the circumscribed square. The intersections of the spheres with the vertical spans passing through the sides of the squares are formed by arched beams, which spring from the capitals of short cylindrical columns. The cupolas are 4½ inches thick, and are made of concrete composed of cement clinker finely broken up; they are reinforced by a layer of expanded metal with a lattice work of bars. Members of the institution had a good opportunity to examine this structure, as one of the banquets during the meeting was given in the Renommée Hall.

An interesting application of reinforced concrete was also described in the widening of La Boverie Bridge at Liége. Particulars were also given of another bridge, built upon the Hennebique system; the length between abutments was 260 feet, and comprised a central span of 180 feet and two side spans. The total width of the roadway was 32·8 feet. An interesting feature about this bridge is the design of the foundations, and the way they were erected by mechanical compression of the soil. The piers and abutments rested upon a group of concrete piles driven deeply into the bed of the gravel, which thus became strongly compressed. The concrete piles were reinforced by vertical bars of steel which were continued into the piers and abutments, so that the whole was solidly bound together. By this method the advantage was obtained of solidly rooting the bridge into the earth, so that it had a resistance amply sufficient in case of a floating accumulation of ice, such as would temporarily transform the bridge into a dam. A skew bridge, also on the Hennebique system, was referred to, and a description was also given of a framework for lead chambers at the chemical works of the Engis Co. In the brief discussion which followed this paper, Mr. W. H. Maw suggested that it would be interesting if experiments could be made upon the effect of tension upon bars held in concrete. He had heard that a better hold of the concrete was obtained if the bars were previously treated to a wash of cement.

Mr. Mellanby's paper on the efficiency of the steam jacket was next read. This paper may be said to form part of a series of contributions on the same subject which have been given by various authorities during recent times. The results of a series of somewhat elaborate trials were given, from which the following general results may be taken. A compound engine, with boiler pressure at 150 lb., may be worked with the mean pressure referred to the low-pressure cylinder of about 40 lb. per square inch without any loss of efficiency in terms of the brake horse-power. Steam jackets have their maximum efficiency when the whole of the high-pressure and the ends of the low-pressure cylinders are jacketed with high-pressure steam. When jackets are applied to the high-pressure cylinder, the total indicated horse-power is slightly reduced, but when applied to the low-pressure cylinder the total indicated horse-power is considerably increased. Jackets have little effect in the high-pressure, but have considerable effect in the low-pressure cylinder upon initial condensation. The temperature supplied to the cylinder walls next to the steam must be considerably less than that of the steam, because, firstly, the actual "missing quantity" is much less than it would have been had the steam and metal gone through the same temperature changes, and secondly, because the mean temperature of the metal is higher than that of the steam. The author concluded that the greater part of the "missing quantity" must be due to leakage, and not to initial condensation, in this respect agreeing with the conclusions of Messrs. Callendar and Nicolson.

A somewhat extended discussion followed the reading of this paper. It was opened by Mr. V. Pendred, who said that compression in the cylinder had a considerable effect. If the compression corner of the indicator diagram was square, the utility of the jacket appeared to be small, but if it were rounded off by compression jacketing appeared to be more effective. Mr. Saxon, of Manchester, took exception to the statement as to a mean effective pressure of 40 lb. being the most efficient for a compound engine; he considered that the ratio of the cylinders should be taken into account. Mr. Henry Davey did not regard the results obtained as a guide for engineers, on account of the bad performance of the engine. Mr. Mark Robinson confirmed the author's opinion in regard to a mean pressure of 40 lb., and, in reply to a remark of Mr. Saxon's, said that the size of the cylinders should be in accordance with the power needed, and their ratio should be governed by the conditions of working.

On the second day of the meeting the first paper taken was a contribution by Mr. R. Mathot on large gas-engines. This was a long and interesting paper, containing a considerable amount of historical matter, and dealing with many of the details of construction by Continental makers in the design of large gas-engines, which have formed so prominent a feature of the engineering of Germany and Belgium within the last few years. The paper was illustrated by a number of engravings and diagrams, and results of engine tests were given in a table. Although English engineers early took the lead in the manufacture of gas-engines of moderate size, they have been to some extent left behind by Belgian and German manufacturers in regard to large gas-engines using blast-furnace gas; and even such of the latter as have been constructed in England have been mostly to German designs. It would be impossible in a report of this nature to give an account of the many details of construction dealt with by the author, especially without the aid of the numerous illustrations by which the paper was accompanied.

The discussion that followed the reading of the paper mainly consisted of a speech by Mr. Crossley, of Man-

chester, who defended the position of the English gas-engine makers, pointing out what had been done in the past. He did not, however, deny that the Continental makers were in advance of the English makers in regard to the size of the gas-engines manufactured.

The remaining paper was Prof. Lilly's contribution on the strength of columns, but the time for adjournment having arrived, this was only read in brief abstract, and was not discussed.

A large number of excursions and visits to works in the neighbourhood of Liége had been arranged by the local committee. Visits were also paid to the exhibition, and there were the usual social functions, including the reception, the dinner at the Renommée Hall already mentioned, and the institution dinner held at Liége. Thursday was entirely given up to these excursions, and on Friday members travelled to Antwerp, where they viewed the extensive docks of that city and some of the works in the neighbourhood. This brought a very successful meeting to a close.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Dr. Ritchie, Fellow of New College, the present reader in pathology, has been constituted professor of pathology so long as he continues as reader. Dr. A. J. Herbertson, non-collegiate, has been appointed university reader in geography.

The Rev. H. T. Morgan, Trinity College, has offered to continue the unfinished carving in the corridors of the university museum. Much of the elaborate plan for the sculptural decoration of the museum, undertaken in 1860, has remained uncompleted, and the Rev. H. T. Morgan has generously undertaken to provide for the carving of the capitals and corbels of at least two of the four upper corridors. The delegates propose to continue the original plan, according to which the capitals were to represent various plants in systematic order.

On June 20 a deputation from the medical graduates of the university, Sir William Church, Dr. Sharkey, Dr. Shornstein, Dr. Collier, and Mr. Whitley, presented an address to the Vice-Chancellor urging the importance of pathology in the medical curriculum of the university, and stating the steps that have been taken to provide permanent endowment for the teaching of this subject. A "pathology endowment fund" has been started, and an appeal that was limited to members of the profession has resulted in the contribution of more than 500*l*. A member of the university, who has already given 1000*l*. towards the endowment of a pathology chair, has offered to cover all subscriptions from the medical faculty by an equal amount.

IT is announced that General W. J. Palmer, of Colorado Springs, Col., and Mr. Andrew Carnegie have given respectively 20,000*l*. and 10,000*l*. as a nucleus to the 100,000*l*. endowment fund for Colorado College.

MR. T. P. BLACK has been appointed demonstrator in physics in Armstrong College, Newcastle-upon-Tyne. Mr. Black was a student of the college from October, 1900, to June, 1903, when he was elected to one of the Royal (1851) exhibition scholarships.

WE learn from *Science* that the proposed affiliation of the Massachusetts Institute of Technology with Harvard University was approved at a meeting of the corporation of the institute on June 9. It was agreed to accept the terms of the agreement recently drawn up by the committee of the two institutions. Before the agreement can become effective the corporation and overseers of Harvard University must take action, and several legal questions must be settled.

THE committee appointed to inquire into the present condition of fruit culture in Great Britain, and to consider whether any other measures might with advantage be taken for its promotion and encouragement, has reported to the Board of Agriculture in favour of the establishment of a special sub-department to deal with matters connected with the fruit industry. The main recommendation is that there should be two branches of such sub-department—(*a*) a bureau of information, (*b*) an experimental fruit farm. It is further proposed that horticulture should be taught in elementary schools in country districts, that such schools should have gardens attached wherever possible, and that the attention of local education authorities should be directed to this, and also to the desirability of encouraging the study of practical horticulture in training colleges.

THE programme of the summer meeting of university extension students, which is to be held at Oxford in August, has now been published. The lectures in the natural science section will be devoted to an explanation of the scientific method and to the illustration of its application to scientific work. General introductory lectures will be delivered by Prof. T. Case, on the scientific method as an operation of the mind, and by Prof. F. Gotch, F.R.S., on the development of the scientific method. Special lectures illustrative of the applications of the scientific method to numerous branches of science have been arranged, and these lectures will be directed to show the extent to which the general conception of the particular science has been developed by the use of the scientific method, and the way in which the method is used in the experimental investigation of some group of phenomena. Among the varied list of lectures from which students may choose we notice those by Prof. W. F. R. Weldon, F.R.S., on variation and heredity; by Prof. C. S. Sherrington, F.R.S., on a general survey of physiology and psychophysics; by Prof. W. M. Flinders Petrie, F.R.S., on crucial instances in archæology; and by Dr. G. J. Burch, F.R.S., on modern conceptions of matter.

MR AILWYN FELLOWES, President of the Board of Agriculture, presided at an agricultural conference held at Aberystwyth last week. The object in view in holding the meeting was the extension and development of the work of the agricultural department of the University College of Wales by the establishment of a more definite connection between its extension work and that done inside the college, and by better organisation of the department of agriculture itself. Mr. Fellowes said that the Board of Agriculture has been able to give 800*l*. a year to Aberystwyth College and 200*l*. a year towards the college farm which was opened the same day. The college is also largely aided by the residue grant which since the year 1890 has been handed over to the county councils of the kingdom. In the counties connected with Aberystwyth College, one-sixth of the residue grant has been given to agricultural education. Mr. Fellowes said he hoped, as time went on and as Imperial funds improved, that the Board of Agriculture will be able to do more for agricultural education and for agricultural colleges. He strongly commended the suggestion that a descriptive pamphlet should be issued by the college authorities setting forth what are the proceedings of the college and what young men are able to learn there. It was decided to ask the county councils to appoint representatives to consider the details of a scheme of organisation for the agricultural department at a conference to be held in October. The following resolution was passed:—that this conference desires to record its warm gratitude to the Board of Agriculture for the invaluable aid it has rendered to agricultural education in the counties affiliated to the University College of Wales at Aberystwyth. The conference is of opinion that the results already attained and the response to the help and guidance received from the Board by the local authorities out of their limited resources constitute a strong claim for largely increased grants from the central Government towards agricultural education, which is a matter of the highest importance in the interests of the kingdom and the Empire at large. In the afternoon Mr. Fellowes opened the recently acquired college and counties' training farm, which is situate about four and a half miles outside Aberystwyth, and has an area of 200 acres.

SOCIETIES AND ACADEMIES.

LONDON.

Geological Society, June 7.—Dr. J. E. Marr, F.R.S., president, in the chair.—The microscopic structure of minerals forming serpentine, and their relation to its history: Prof. T. G. **Bonney** and Miss C. A. **Raisin.** The authors embody their investigations in the following conclusions:—(1) That both a tint and pleochroism are accidental rather than essential characteristics of antigorite. (2) Neither are low polarisation-tints characteristic, unless two mica-like minerals exist, otherwise indistinguishable. (3) That it is doubtful whether any hard and fast line can be drawn between antigorite and the more fibrous forms in ordinary serpentine rocks. (4) That the most typical antigorite appears when the rock has been considerably affected by pressure, but it becomes less so when the latter has been very great. (5) That so far from the nearly rectangular cleavage of augite originating the "gestrickte struktur," it is worse preserved than any other original one in the process of serpentinisation. Typical antigorite, however, apparently is rather more readily produced from augite than from the other ferromagnesian silicates, but is more directly a consequence of pressure than of chemical composition.—The tarns of the Canton Ticino: Prof. E. J. **Garwood.** The lakes dealt with comprise the larger Alpine tarns which occur in the Canton Ticino. Most of these drain into the Ticino basin; one or two, however, flow into the Reuss or the Rhine. These lakes owe their origin, when they are rock-basins, to the presence of lines of weakness, along which in many cases solution has taken place, while in some shallow tarns ice may have removed detached fragments; but in no case has a lake been found which can reasonably be assigned to ice-excavation independent of rock-structure.

Mineralogical Society, June 14.—Prof. H. A. Miers, F.R.S., president, in the chair.—The chemical composition of lengenbachite: A. **Hutchinson.** A quantitative analysis of the new mineral from the Binnenthal recently described by Mr. R. H. Solly leads to the formula $7PbS.2As_2S_3$, part of the lead being replaced by silver and copper, and part of the arsenic by antimony.—The chemical composition of hutchinsonite: G. T. **Prior.** Chemical examination of this new and extremely rare mineral from the Binnenthal described by Mr. R. H. Solly showed that it could be added to crookesite and lorandite as a third mineral containing the rare element thallium as an important constituent. Quantitative analysis, made on a small amount of material (about 70 mg.), showed the presence of about 20 per cent. of thallium, and suggested the formula $(Tl,Cu,Ag)_2S.As_2S_3+PbS.As_2S_3$.—The identity of the amiantos of the ancients with chrysotile: Dr. J. W. **Evans.** The principal source of amiantos appears to have been Cyprus. Specimens brought by Prof. Wyndham Dunstan from the ancient workings on the slopes of Mount Troodos prove to be chrysotile, and not tremolite asbestos. A chemical analysis by Mr. G. S. Blake confirmed this result.—Gnomonic projection on two planes at right angles: Dr. J. W. **Evans.** By means of these projections and the rotation of one plane on an axis at right angles to the other, simple solutions of crystallographic problems are obtained.—The **President** exhibited supersaturated solutions of sodium nitrate showing the transition from the metastable condition, in which crystallisation is only possible in the presence of solid crystals, to the labile condition, in which the liquid can crystallise spontaneously.

Physical Society, June 16.—Prof. J. H. Poynting, F.R.S., president, in the chair.—On the ratio between the mean spherical and the mean horizontal candle-power of incandescent lamps: Prof. **Fleming.** This paper contains a theoretical deduction from first principles of experimental results given by Mr. G. B. Dyke in a paper read before the Physical Society on November 11, 1904, respecting the ratio of the M.S.C.P. of incandescent electric lamps to the M.H.C.P. taken when the lamp was rotating round a vertical axis. In the case of nine different types of electric glow-lamps, this ratio was found to be a number near 0·78. The author shows, by discussing the simple case of linear filament, that the ratio of the M.S.C.P. to the horizontal candle-power for this last case must be represented by the value $\pi/4=0{\cdot}785$, and hence that the constant ratio found experimentally by Mr. Dyke necessarily follows as a simple consequence of the fact that the light sent out in any direction from each unit of length of an incandescent filament varies as the cosine of the angle of inclination of the ray to the normal to the filament. In the paper it is shown also how a simple correcting factor may be obtained for reducing the actual horizontal candle-power of a linear filament of finite length to the candle-power in the same direction which would be found if the elements of the filament were concentrated on the axis of the photometer and all normal to it.—The electrical conductivity of flames: Dr. H. A. **Wilson.** The paper contains an account of a series of experiments on the conductivity of a coal-gas flame for electricity between platinum electrodes immersed in the flame. The variation of the current with the distance between the electrodes and the fall of potential along the flame are investigated by using a special burner producing a long narrow flame. The burner consists of a fused quartz tube with a series of small holes parallel to its diameter. The electrodes are two parallel discs of platinum, one fixed at one end of the flame, and the other capable of movement horizontally in the flame, so that it can be placed at any desired distance from the fixed electrode. The current through the flame was measured by a moving coil galvanometer, and the potential difference between the electrodes by an electrostatic voltmeter. The quartz-tube burner being a good insulator enables a current to be passed from one end of the flame to the other without fear of any of it going through the tube instead of through the flame. It thus enables the effect of putting salts into different parts of the flame to be easily studied.—Contact with dielectrics: Rollo **Appleyard.** Among the conclusions arrived at are the following:—(*a*) Except in the case of homogeneous dielectrics, it is misleading to deduce specific values referred to unit cube of the material from the results of tests on sheets. (*b*) With tin-foil electrodes, the apparent resistance of press-spahn diminishes as the load increases, and it attains a fairly constant value at a load of 400 grams per cm.^{2}. (*c*) If, with tin-foil electrodes, the load is gradually diminished after a load of 543 grams per cm.^{2}, the resistance gradually rises, but the rise is less rapid than the diminution in the former case (*b*). (*d*) When the full load with tin-foil electrodes is again restored the resistance falls to its minimum value. (*e*) For small loads, with tin-foil electrodes, the 2nd-minute deflection is in general greater than the 1st-minute deflection. As the load increases, a point is reached at which these deflections become approximately equal. For loads greater than about 360 grams per cm.^{2}, the 1st-minute deflection is in general greater than the 2nd-minute deflection. (*f*) Increase of voltage, with tin-foil electrodes, especially with small loads, behaves like increase of load, apparently increasing the contact area, and diminishing the observed dielectric resistance. Load, voltage, and the normal effect of "absorption" thus combine to determine the ratio of the 1st-minute deflection to the 2nd-minute deflection. (*g*) When mercury electrodes are used, the dielectric-resistance, as measured at different voltages, is sensibly the same, even for abrupt and great changes of voltage. (*h*) When mercury electrodes are used, the 2nd-minute deflection is in general never greater than the 1st-minute deflection. The inference is that when, with tin-foil electrodes, the converse is the case, it arises from imperfect contact, and not from the material itself. (*i*) When mercury electrodes are used, the dielectric-resistance, as measured with a voltage applied in a given direction, is sensibly the same as that measured with the voltage reversed, and this equality appears to become greater after a few reversals. (*j*) There is a critical load at which tin-foil electrodes yield fairly accurate results. With greater loads there is danger of crushing the material. With a less load the contact is faulty.—The pendulum accelerometer; an instrument for the direct measurement and recording of acceleration: F. **Lanchester.**—A new form of pyknometer: N. V. **Stanford.**

Royal Meteorological Society, June 21.—Mr. Richard Bentley, president, in the chair.—Normal electrical phenomena of the atmosphere: G. C. **Simpson**. In no branch of physics has the discovery of "ions," "electrons," and "radio-activity" produced a greater revolution than in that devoted to atmospheric electricity. In this paper the author endeavoured to state the chief line along which during the last few years investigations have been made and the conclusions arrived at, and also to point out some of the problems awaiting solution. The amount of radio-active emanation in the lower regions of the atmosphere is increased by all those meteorological conditions which tend to keep the air stagnant over the earth's surface. The meteorological conditions which either cause or often accompany stagnant air are calm, low temperature and high relative humidity, while, on the contrary, high winds, high temperature, and low humidity generally accompany the mixing of large masses of air. This all agrees with the observed facts that the atmospheric radio-activity increases with falling temperature, rising humidity, and increasing wind strength.—Two new meteorological instruments: G. P. **Ferguson**. The instruments described were:—(1) automatic polar star light recorder for recording the amount of cloudiness at night; and (2) the ombroscope, an instrument for determining the time and duration of rain. Both these instruments are in use at the Blue Hill Observatory, Mass., U.S.A.

PARIS.

Academy of Sciences, June 19.—M. Troost in the chair.—On the preparation and properties of nitryl fluoride: Henri **Moissan** and M. **Lebeau** (see p. 206).—On some alkyl thujones and the combinations of thujone with aromatic aldehydes: A. **Haller**. The thujone was converted into its sodium derivative by means of sodium amide in ethereal solution, and this acted upon by the alkyl iodide. The preparation and properties of methyl, ethyl, propyl, and allylthujone are described, the special object of the work being to study the influence of the introduction of the alkyl group on the rotatory power. Thujone was also condensed with benzaldehyde, anisaldehyde, and piperonal, the effect in these cases being an enormous increase in the rotatory power. Special experiments were made to see if in the course of the work the thujone had been converted into isothujone, but this was found not to be the case. An improvement in the method of preparation of isothujone from thujone is also described.—Observations on the Giacobini comet (1905 *a*) made with the large equatorial of the Observatory of Bordeaux: Ernest **Esclangon**. The observations were made on May 2 and 9.—On the influence of concentration on the magnetic properties of solutions of cobalt: P. **Vaillant**. If A be the coefficient of magnetisation of a solution containing N equivalents of water and n of salt, then $A=K'N+Kn$, where K and K' are the coefficients characteristic of the water and the salt. It was found that the value of K was nearly independent of the concentration and of the nature of the salt, the chloride, nitrate, and sulphate being studied. The slight variation of K observed would appear to be due to ionisation.—On a basic ferric sulphate: A. **Recoura**.—The chemical properties of the anhydrous chloride of neodymium: Camille **Matignon**. Hydrogen at 1000° C. has no action upon the dry chloride, no trace of a subchloride being detected. Oxygen slowly converts the fused chloride into the oxychloride, NdOCl, water giving rise to the same substance. Hydriodic acid slowly converts the chloride into the iodide, and the bromide is formed with hydrobromic acid by a similar reaction.—On a method for determining the specific heats of solutions. The molecular heat of good and bad electrolytes: P. Th. **Muller** and C. **Fuchs**. The liquid is heated by a glass spiral containing mercury through which a constant current is passed, water and the solution being alternately introduced into the calorimeter. The causes of the differences between the specific heats of solutions of electrolytes and non-electrolytes are discussed.—Researches on the mercury formates: Raoul **Varet**. A thermochemical paper.—On some new nitrodinaphthopyranic derivatives: A. **Robyn**.—On sparteine; the stereoisomerism of the two iodomethylates: Charles **Moureu** and Amand **Valeur**. These two iodomethylates cannot be distinguished by their behaviour on heating, as they both split up quantitatively into methyl iodide and sparteine, and hence the author regards the isomerism as of a stereochemical order.—The influence of electrolytes on the mutual precipitation of colloids of opposite electrical sign: Larguier **des Bancels**.—On a new form of tartrate of thallium, and on isomorphous mixtures of the tartrates of thallium and potassium: Jean **Herbette**. Although the tartrates of thallium and potassium belong to different crystalline systems, mixtures of these salts exhibit a true isomorphism; the properties of the mixed crystals of these two salts do not vary in proportion to the chemical composition. A case analogous to this has already been pointed out by Groth for a mixture of potassium chlorate and permanganate.—The action of liquid air on the life of the seed: Paul **Becquerel**. The resistance of seeds to low temperatures depends entirely upon the quantity of water and gas contained in their tissues. If this quantity of water and gas is sufficient, the cold disorganises the protoplasm and nucleus in such a manner that life is impossible, but if the protoplasm has by drying attained its maximum concentration, it completely escapes the action of the low temperature, and the seed preserves its germinating power.—An enemy of the Tonkin coffee plant, the Xylotrechus of the dry bamboo: Louis **Boutan**.—Researches on the ethnology of the Dravidians. The anthropological relations between the mountain tribes and the castes of the plain: Louis **Lapicque**.—On the presence of graptolith schists in the High Atlas of Morocco: Louis **Gentil**.—On the formation of the Rochefort Cave (Belgium): E. A. **Martel**.—On the evolution of the fossil mammals: Marcellin **Boule**. A reply to a criticism of M. Depéret.—The meteorology of total eclipses of the sun: W. **de Fonvielle** and Paul **Bordé**. Remarks on the work done by Sir John Elliot on the lowering of the temperature during the eclipse of the sun.

THURSDAY, JULY 6, 1905.

THE EMPIRE AND UNIVERSITY LIFE.

WE publish to-day a statement signed by more than forty professors and heads of departments of the University of Oxford setting forth a scheme for large increase in the facilities for research and for teaching. We have no hesitation in stating that these forty signatures include the majority of Oxford workers with a reputation for learning which extends beyond the borders of that ancient university. They also represent, with singular completeness, the varied lines of research which happily are pursued at Oxford; and it is an encouragement among the many unsatisfactory features in the intellectual life of the nation that they are ready and willing to stand side by side, each sympathising with the needs of other workers, each desiring to grant the fullest opportunities for research on the broadest lines.

They doubtless feel in Oxford, as we recognise in London, and as Britain generally is beginning to know, that the real conflict in this country is not between science and classics, between theology and philosophy, or between the true followers of any branches of learning, but that the great educational struggle of our time and race is of an utterly different kind. On the one side are ranged those who hold that the much needed intellectual inspiration of our youth can only be received in an atmosphere of research, can only be given by men who are themselves researchers; on the opposite side stand those who uphold the ancient Chinese and the modern British educational methods. We recognise to the full the Imperial importance of the subject. Young men instructed by purveyors of second-hand word knowledge are not likely to develop the germs of imagination and originality, and to deal effectively with the problems presented in the modern world which deals with things; and the time in which such development is generally possible is all too brief. When once the critical period of intellectual growth has been devoted solely to the collection and re-collection of material for the examiner, any awakening of original power is rare indeed. We have merely created one Briton the more incapable of using his birthright, out of sympathy with the movement which would help others to gain what he has lost; and his want of sympathy may mean a great deal. He may become a journalist and help to frame the opinion of the nation, he may enter Parliament and help to marshal the educational forces upon which our future existence most surely depends, he may be a power in the Treasury and help to determine the expenditure of the national income, he may become a schoolmaster or a college tutor and do unto others even as he has been done by.

It cannot be disguised that things are in many respects worse than they were half a century ago. The University Commissioners of 1850 said of Oxford:—"It is generally acknowledged that both Oxford and the country at large suffer greatly from the absence of a body of learned men devoting their lives to the cultivation of science, and to the direction of academical education."

The commissioners of a quarter of a century later did, indeed, largely increase the number of university professors, but it left them powerless—muzzled lions chained by the leg. The whole power of influencing the passing generations of young men it left in the hands of a score of independent corporations—nearly all of them ancient, and with noble traditions of high learning and profound research; but, in the intellectual backwater of our time, each has strained to become a petty university and the successful rival of all the other petty universities—the successful rival, that is, in the qualities developed by examination, and in nothing higher. To this end each has freely spent its endowment in entrance scholarships to compete with others for the men who will do best in examinations, and each has striven to secure, before and beyond all others, the most successful purveyor of knowledge which will be useful in examinations. We say, intentionally and deliberately, that each college *has* done these things, but are far from implying that all of them have no higher aims at the present time. We are only too glad to recognise in recent years a change of spirit which has led to significant departures from the scheme of the last university commissioners. Magdalen, New College, and Brasenose have been noble leaders in a noble cause—the return of Oxford to ideals of learning which have been suppressed, but not altogether killed, by a false and injurious educational system. We gladly recognise clear evidence of the same spirit in other societies, and we are well aware that others, again, strongly desire to make provision for the highest learning, but are unable to do so while their whole available funds barely suffice to enable them to keep their place in the unfortunate and wasteful inter-collegiate competition which dominates both our ancient universities. There is, however, one college in which the necessity for such competition is reduced to a minimum, and it is precisely here that the last commissioners inflicted the crowning injury upon the intellectual life of Oxford—they set their seal on the existing constitution of All Souls. A college almost without the responsibility and the care of undergraduates is created, it would seem, to be the home of the highest learning and research. And what is it? Well, apart from a distinguished professoriate, a generous assistance to the Bodleian, and a rare and occasional election of men of learning to her fellowships—for all of which we freely and gladly express our gratitude—All Souls merely exists in order to encourage the worst features of an intellectual training which exists by and for examination alone. Only recently the governing body rejected the movement, which happily existed among some of the members, to ask for evidence of original power in the candidates who compete for the fellowships. Yet

All Souls might readily do as much for learning in Oxford by her fellowships as she now does to prevent learning—as she now does to turn the attention of the ablest men towards what will pay in examinations, and to shut their ears to the still small voice of latent imagination and original power. If All Souls gave her two fellowships each year for evidence of research, the ablest of the men studying the subjects of her choice would demand of their teachers inspiration and guidance in the highest work. Where the ablest men lead others would soon follow, and the whole intellectual atmosphere would rapidly change.

All Souls unaided could do an immense deal to induce the other colleges to provide higher teaching, or, even better, to encourage their men to get help outside the college walls. As it is, she provides the strongest of all the forces which chain Oxford to that unhappy infatuation which has had so disastrous an effect on the imagination, the initiative, the resourcefulness of the nation.

The title of this article was chosen in the profound conviction that interests much wider and more important than those of Oxford and Cambridge are at stake. Our ancient universities have heavy responsibilities, extending far beyond their historic walls. Every new university and university college in the Empire draws its teachers from Oxford and Cambridge, and, for good or for evil, moulds the broad features of its intellectual life upon the pattern supplied by these ancient seats of learning.

In the supreme interests of the Empire, as well as of the university itself, we fully sympathise with the aims of those who desire to render Oxford a more efficient instrument of research and the highest and most stimulating teaching, but we have no right to claim their sympathy or support for our own views on university and collegiate life. It may well be that the onlooker sees weaknesses and obvious measures of reform hidden from those on the spot, or appearing to them as a far-off ideal impossible of realisation, at least in this generation. Speaking for those who watch from without, who admire and would preserve and strengthen the truly inspiring elements of the academic life at both our ancient universities, we would gladly see them subject to the following simple, but, as we believe, efficient measure of reform.

The whole of the teaching should be entirely under the control of the university, which in its boards already possesses at least the foundation of the necessary apparatus. The college fellowships should be given in part for university teaching combined with original work and in part for research alone, to be held only during the continuance of investigation. A career would thus be open for originality of a high order, and the ablest men would flock to our ancient seats of learning and render them indeed worthy of the name. Residence in homes of ancient learning would gain added inspiration when the greatest traditions of the past were renewed and maintained. Even with things as they are, Oxford and Cambridge, though much injured by competitive examinations, have been far less injured than England in general; and this they owe to the residential system. Little thought of, perhaps neglected, by the builders, the head-stone of the educational edifice is here to be found. Where mind meets mind in the free intercourse of youth there springs from the contact some of that fire which, under our present system, is rarely to be obtained in any other way; and not only this, but many other priceless advantages in the battle of life are also conferred. To these influences we owe in large part all that is best in the English character, and so valuable are the qualities thus developed, or at least greatly strengthened, that we regard residential colleges as essential to the success and usefulness of the newer universities. The changes we have advocated in the older universities would only add to this beneficent system increased power for good by substituting for the barren pride of first classes and university prizes the enthusiasm for a society which nobly holds its own in those achievements which bring renown wherever the advancement of learning is held in honour—a sufficient answer to the contention that to deprive a college of teaching is to render it a boarding-house and nothing more. That the advancement of learning is the desire of those who have signed the memorial we do not doubt, however much they may disagree with the methods here suggested for the attainment of their ends. On our part we feel such confidence in the beneficent influence of the increase in efficiency for which they plead, that we should gladly see funds provided for the purpose.

In former centuries the highest learning was encouraged in this country by the munificence of "founders and benefactors"; and we are glad to know that one of the needs set forth in the accompanying statement has already been generously met, and even more than met, by the establishment of a department presided over by a Beit professor of colonial history. But the signs of the times do not encourage us to anticipate any very large or fruitful following of this fine example; and we see no prospect of carrying out the suggested scheme in anything like completeness, except by a re-arrangement of the revenues of the university and the colleges, or by the action of a Government which is convinced that the national well-being is imperilled, the national existence at stake.

THE SARCODINE FAUNA OF DEEP LAKES.

Les Sarcodinés des Grands Lacs. By Eugène Penard. Pp. 133. (Geneva: H. Kundig, 1905.)

DR. PENARD'S enthusiastic and minute investigations into this group of the Protozoa are well known. In the course of many years' study of the Sarcodina of the Lake of Geneva and of the surrounding country, he became convinced that there is a special sarcodine fauna of deep lakes. The facts on which he founded his theory, already embodied in his

two great monographs of the Rhizopods and Heliozoa, are here presented in a form more accessible to the student. About fifty species and varieties are described and figured, the majority being peculiar to deep lakes, the others characteristic of, though not confined to, deep lakes.

On looking over the diagnoses of the species, it cannot fail to be remarked that many of them are distinguished by very trivial differences from other known species. Considering the intolerable burden of synonymy in zoological nomenclature which results from the practice of describing species on insufficient grounds, it is a pity that Dr. Penard should have conferred a specific name upon a form (*Difflugia curvicaulis*, Penard) which he naïvely admits he regards as scarcely even a fixed variety. Other instances are not wanting in the volume of species which seem to be of very little value. It is obvious that he makes insufficient allowance for the recognised variability of the species of the group. He puts too much reliance on size as a specific character, and gives an exaggerated value to minute differences in the size and form of the scales which encrust many species.

Making all allowance for the slight differences on which he separates the abyssal species from the related species of shallower waters, it appears that there is really some considerable amount of peculiarity among the abyssal Sarcodina. Species tend to appear in the abyssal region under different forms or varieties from those found elsewhere. We would ask, however, whether this peculiarity is any greater than one would expect from the influence which must be exerted by the very different environment upon the individuals produced in this region?

Of interest in this country is Dr. Penard's assertion that some representatives of the abyssal fauna of the Swiss lakes have been found by him in Loch Ness. The difficulty of accounting for the passage of abyssal forms from one lake to another is just touched upon, and dismissed with the short statement that several of the species have also been found at the margins of the lakes, as well as in the depths. One is tempted to make another explanation of this fact, and say that it proves that they are not peculiarly abyssal. Dr. Penard does not say whether he regards this coming to the shore as a normal mode of migration of abyssal species.

In the special case of Loch Ness, there are facts which make it difficult to believe that the abyssal Rhizopods are peculiar species. No abyssal species of any other class has yet been found in Loch Ness. Some of the forms which are regarded as purely abyssal in the Swiss lakes are found in the shallow bays of many Scottish lochs, and even in peat bogs. This may prove an interesting fact in distribution if it can be shown that species which are superficial in Scotland have to descend to some depth in Switzerland in order to find congenial conditions of temperature. Among Dr. Penard's abyssal forms which have been found in Scottish moss may be mentioned *Heliopera petricola*, var. *amethystea*, Penard, and *Cyphoderia ampulla*, var *major*, Penard.

Making due discount for his too high appreciation of minute differences, and appraising his species at our own value, this volume is valuable to students of the Sarcodina, as there is no question of Dr. Penard's painstaking accuracy of observation. His descriptions are clear and concise, while the illustrations in the text are excellent.

STEAM TURBINES.

(1) *Steam Turbines, with an Appendix on Gas Turbines.* By Dr. A. Stodola, of Zurich. Translated from the second revised and enlarged German edition by Dr. L. C. Loewenstein. Pp. xvi+434; illustrated. (New York: D. Van Nostrand Company; London: Archibald Constable and Co., Ltd., 1905.) Price 21s. net.

(2) *Bau der Dampfturbinen.* By Prof. A. Musil. Pp. 6+233. (Leipzig: B. G. Teubner, 1904.) Price 8 marks.

(1) THE steam turbine has for some years now, thanks to the inventive genius of Mr. Parsons, become a formidable rival of the reciprocating steam-engine on land, and the past three years have seen a rapid increase in its use for marine purposes. On cross-channel steamers there is no doubt that in a few years it will completely oust its rival, while the adoption of this type of engine for two of the Allan line steamers, and the decision to use steam turbines for propelling the great Cunarders now being built, probably herald the approach of the day when on these big liners also the reciprocating marine engine will be entirely displaced.

It is not surprising, therefore, that there has grown up a rapid demand for good text-books on the steam turbine in which both the theory and the constructive details of the numerous types now on the market are fully dealt with. In addition to numerous papers and articles which have been printed in the Transactions of our leading engineering societies and in the technical journals, we have had two editions of Mr. Neilson's book, and now, by this English translation, the latest edition of Dr. Stodola's classic work is made available to British engineers.

In his preface to the second edition, Dr. Stodola points out that he has been able in the period which elapsed since the issue of the first edition to investigate experimentally several important problems untouched in the first edition, as, for example, the frictional resistance of turbine wheels in air. In the first section, after dealing with the elementary theory of the steam turbine, a concise and clear classification is given of the various types which have so far been practically successful. The more advanced thermodynamic problems which are met with in the theory of the steam turbine form the subject of the second section, and details are given of a series of valuable experiments on the flow of steam from orifices; these experiments are of great importance, and the results are very striking, and will undoubtedly prove of great value to those engaged in the design of diverging nozzles for turbines. In connection with this chapter, Mollier's diagrams for the properties of saturated steam are explained; these diagrams have been reproduced, and, for the English edition, similar

diagrams, expressed in English units, have been prepared by the translator. The design of the details of the more important types of turbines is then investigated, and such details as the shape, the construction, and the strength of the blades, and the design of the bearings of the shafts are fully dealt with.

In section iv, a full description is given of the various types of steam turbine which have so far been constructed and have been practically successful, and, in the case of several, the results of experiments by trained observers are given in detail. This portion of the book will be found of particular value to users of steam power who are anxious to have some knowledge of the relative merits of the various types of turbine now on the market. The application of the steam turbine to marine purposes is scarcely dealt with in as full and comprehensive a manner in Dr. Stodola's book as the rest of the subject, and a little more information might well have been given as to the relative merits of the steam turbine and the reciprocating engine for various purposes.

The last section of the book deals with some of the more advanced scientific problems, treated largely from a mathematical point of view, which occur in connection with the theory and construction of the turbine. We might instance such problems as that of the distribution of pressure in any cross section of an expanding gas or steam jet, the deflection, due to its own weight, of a horizontal disc of variable thickness, and the straightening out of such rotating discs under the action of centrifugal forces.

In an appendix, the possible future of the heat engine is briefly discussed; the main directions in which increased economy may be hoped for appear to be in the decrease of the passive resistances, such as friction, &c, in the supply of the heat to the motor only at the highest possible temperature and in the abstraction of the waste heat only at the lowest possible temperature, and in the avoidance, so far as possible, of all non-reversible changes of condition. Dr. Stodola is of opinion that in the future a heat motor which combines the high thermal results of the gas engine with the constructive advantages of the steam turbine will supplant all other types. Such a motor will be found in the gas turbine, a motor which at present has not reached practical constructive stages.

(2) After a brief account of the history of the steam turbine from the days of Hero, and a discussion of the lines upon which recent invention has proceeded, Prof. Musil gives a very useful bibliography; then, as is usual in books on this subject, there follows a classification of the various steam turbines now in use. The theory of the well known Laval nozzle is then dealt with mathematically, and the proportions of such nozzles are worked out in detail; the results of experimental investigation into this question are given, and the effect on the flow through such nozzles of superheating the steam is discussed. The thermodynamic problems involved in this branch of the theory of the turbine are also treated by the author with the aid of entropy diagrams.

The remainder of the book is devoted to detailed descriptions of several types of turbines, beginning with the Laval, which is described in detail with a number of illustrations. The important problems due to the use of a flexible shaft in this turbine are investigated, also the question of the governing of the turbine. The steam consumption of this type when under test is given in a series of tables, and the relation of the actual steam consumption to the theoretical is dealt with in some detail. The second type of turbine taken up is the Parsons, again illustrated with a number of well drawn plates, and here also the question of the governing of the turbine forms an important section; details of the actual steam consumption under varying loads are given, and the results have been put into the form of a series of curves, which will be of great use to the student.

It may be well to point out that Prof. Musil expressly excludes from the scope of his text-book the application of the steam turbine to marine purposes. The other types of turbines which are dealt with by Prof. Musil include the Zoelly, the Riedler-Stumpf, the Curtis, and the Rateau. For each type good descriptions of the mechanical details are given, with very clearly drawn illustrations, and in the case of the Zoelly and the Rateau results of tests are also given. Prof. Musil's book will be found of especial value by students in engineering colleges, and by draughtsmen in those engineering works where turbines are now built.

T. H. B.

OUR BOOK SHELF.

An Angler's Hours. By H. T. Sherringham. Pp. xii+264. (London: Macmillan and Co., Ltd., 1905.) Price 6s. net.

MR. SHERRINGHAM deserves the thanks of all anglers who have an idle hour and no fishing for having re-published his essays in book form, and he who is forced by sad circumstances to enjoy his fishing vicariously will find his time well spent in our scribe's company. There is a pleasant and old-world flavour in his style; whether he rises early to catch tench while the dew is still thick, or drowses away his Sunday afternoon in the July heat of a sunny garden, he is an entertaining companion, who boldly confesses to his crimes in the first person or conceals his triumphs, like Julius Cæsar, in the third with equal art. But there is instruction in his essays too, such mild instruction as may best suit an idler, and much shrewd observation of the habits of fishes delicately imparted in pointing the moral of a failure or adorning the tale of a success.

Many important considerations are thus put forward and discussed; for instance, the possibilities of the fly as a lure for other fish than trout and their kind, and the hopes held out to the fisherman who finds himself by some sluggish southern stream if he will only not despair but go forth and tempt the Cyprinids that haunt its troutless waters with flies and tackle suited to their tastes.

Again, there is the harmless, necessary worm; Mr. Sherrington handles him gently (especially when dragging him from his burrow), and adjures us to treat him as a friend in need and no mere despicable device for luring fish to an undeserved and unedifying end. We may be cursed with the instincts of a poacher, but must confess to a leaning towards that conception of the angler's art which advocates the

removal of fish from the water by the most effective means if fish are wanted, and by the most pleasant if amusement is our aim or if the waters hold few fish. We recall a schoolboy who fished for loaches with a gentle if he wanted loaches, but used a kitchen fork tied to the end of a stick if he wanted sport, and we have known others who rose superior to adverse circumstances, one who found all he wanted with a fly rod and small dace on the Cambridge Backs and another who could glory in the capture of eels with a gaff in the same unpromising water.

Mr. Sherringham has not withdrawn the veil that shrouds his early exploits, and he may have been more orthodox; but now he despairs of nothing, but finds good in all; if there are no fish he can study nature, and if there is no water he can shrewdly meditate on the ways of fish and men; an hour with him and his rod by a troutless tarn is as good as an hour by the Kennet in the mayfly time. We will not attempt to cull passages and quote them, or to draw invidious distinctions between one essay and another, but will leave each idle angler to do this for himself, with a candid admission that our own hours with Mr. Sherringham were all pleasant and instructive, but we should like more of them. A word of praise is also due to the publishers, who have produced a book the size and print of which add to its convenience as an adjunct to a pipe, an easy chair, and idleness.

L. W. B.

Botany of Cook's First Voyage. Illustrations of Australian Plants. By Sir Joseph Banks, P.R.S., and Dr. D. Solander, F.R.S. Part iii. Pp. iv+25; with 75 plates. (Trustees of the British Museum, 1905.) Price 25s.

INASMUCH as Solander was a pupil of Linnæus, this work furnishes a link with the founder of systematic botany, and it is known that Linnæus himself looked forward with great anticipation to the publication of the results of the collections made on this the first voyage of Captain Cook. The expectation was not fulfilled, and although certain of Solander's original descriptions were transcribed for sending to press, the MS. on Australian plants did not even reach this stage. A draughtsman, Sydney Parkinson, accompanied the expedition and executed a number of drawings, of which less than a third were finished for engraving purposes. Parkinson died on the voyage home, and other artists continued the work. The specimens and drawings were available, and were consulted by Gaertner and Sir Joseph Hooker, but unfortunately Bentham failed to do so when compiling his "Flora Australiensis." Possibly Banks was responsible for some of the work, but the text is taken from a MS. by Solander, and this is reproduced with brief notes and determinations by Mr. J. Britten, who has also written the interesting introduction printed with this part. In the notices of the earlier parts reference was made to some of the generic names, and, at a time when the rules of nomenclature are being discussed, it is appropriate to instance the name Banksia, that the majority of botanists associate with a genus of the order Proteaceæ, whereas Mr. Britten, in accordance with his views, adopts Isostylis, and refers Banksia to the genus of the order Thymelaceæ, otherwise known as Pimelea. This is merely quoted as an illustration of the confusion of names which renders it most desirable that a uniform system should be universally adopted. The present volume, with the two preceding parts, completes the Australian plants, and for this worthy tribute to the authors botany is indebted to Mr. Britten for his careful revision and to the British Museum for the production.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Education in Belgium and Holland.

DURING a recent cycling tour in parts of Belgium and Holland, as well as during the outward and homeward voyages on a Dutch trading steamer plying between a neighbouring Cornish port and Amsterdam and Antwerp, I have been greatly struck by several examples of the apparent educational superiority of Holland and Belgium over our own country, and at the present moment these examples may not be without interest to your readers.

(1) We were staying at a little inn near Dinant, in Belgium, and our hostess, seeing us occupied in drying some botanical specimens, brought us the herbarium of her son, a boy of about thirteen. These specimens were admirably dried and mounted, and were labelled with details concerning the characters of the order, &c., in such wise as to constitute a valuable educational asset. On inquiry, we found that the lad was a pupil at the lycée of Dinant, and that botany was a compulsory subject there, although the lad had not yet reached the stage of learning foreign languages. The boy himself was so bright and intelligent, and so brimful of enthusiasm for botany, that we at once supposed him to be exceptionally intelligent; but some old friends of the family informed us that until a year ago he was shy and "lumpish," and that the transformation had been effected by the lycée. Commend me to such schools!

(2) The skipper of the Dutch steamer on which we returned told me that in the elementary schools of Amsterdam the children are taken at intervals to the "Zoo" to receive object-lessons on the animals about which they read at school, and on other occasions are taken into the fields to receive object-lessons on the wild flowers; and what struck me especially was that this "mere sailor"—this skipper of a tramp steamer—fully appreciated the value of such practical instruction as giving an interest and sense of reality to his children's school-work. It was also rather surprising to hear such a man express the opinion that a little knowledge of astronomy rendered certain theological doctrines impossible of belief.

(3) The skipper of the outgoing Dutch steamer explained to me that the standard for mates' and masters' certificates in the Dutch mercantile marine is higher than in ours, there being three stages of mates' certificates instead of our two, and that before taking out a master's certificate it is necessary to attend a course of simple medical instruction for some months—surely a very reasonable regulation. On the subject of Englishmen's usual inability to speak a foreign language, he opined that this inability was due to our laziness—not realising, probably, the absurdities of our traditional school system.

(4) The second mate of one of these steamers—a rough lad of twenty-one—seeing me reading a volume of verse in a well known "series" with distinctive binding, asked me if I knew a book like that with Longfellow's poetry, for he had it at home and liked it! I cannot imagine an Englishman of the same age and status knowing a poet even in his own language, much less a foreign poet.

I must not occupy your space by drawing from these facts the moral that is obvious enough, but will conclude with two statements on which it is not pleasant to reflect. These Dutch steamers have driven out a line of English steamers which formerly traded between Fowey and Antwerp, and now practically monopolise the china-clay trade between these two ports; and of the total crews of forty-one carried by the two boats mentioned above, thirty-nine were Dutchmen and two were Germans from the Dutch border, whereas everyone knows that on English vessels often only a small minority of the crew are English. Are such results surprising?

F. H. PERRY-COSTE.

Polperro, Cornwall, June 22.

The "Bubbling" Method and Vapour Pressures.

IN the course of an endeavour to determine the osmotic pressure of a solution by measuring the relative lowering of its vapour pressure, we have been led to abandon Oswald and Walker's bubbling method on account of its inherent inaccuracy.

As the disabilities of this method seem to have been overlooked, we think that this note may be of use to other workers in the same field.

Oswald and Walker, it will be remembered, bubbled dry air through the solution, then through the water, and absorbed the moisture by means of sulphuric acid. The loss of weight of the water measures the relative lowering of the vapour pressure of the solution, and the gain in weight of the sulphuric acid represents the vapour pressure of the pure solvent, water.

Assuming the air to be at the same temperature throughout, it can easily be seen that the space occupied by a bubble of air, when leaving the solution, will be less than that which the same bubble will occupy when leaving the water, that is, the bubble expands while travelling up the water column, and will have taken up more water vapour than it should. The expansion of the bubble (and consequently the amount of vapour necessary to saturate the space occupied by it) is proportional to the difference in pressure at the top and bottom of the water column. If the total depth of the latter be, say, 6 inches, and the barometer stand at 30 feet of water, then an error of 1 part in 60 is induced.

This can conveniently be verified by passing air through two or more Winkler's tubes filled with water; it will always be found that the exit tube has lost weight. Owing to the form of the equation connecting osmotic and vapour pressures, the effect of the above error is magnified.

BERKELEY.

Foxcombe, near Oxford. E. G. J. HARTLEY.

Luminosity and Colour.

IN conjunction with my other methods of testing colour vision, I have been using Rayleigh's apparatus for matching yellow with a mixture of spectral red and green. I find that the proportions of red and green depend upon the luminosity of the match (both the mixed colour and the simple one being of similar luminosity); for instance, I require two and a half times as much green in the mixed colour when the match is bright compared with a match at a lower luminosity. Some persons make a match which is nearly the same at several luminosities, others require more and more green as the luminosity is diminished, and others when the luminosity is diminished cannot make a match at all. So three normal sighted persons may make a similar match at one luminosity, and at another one may appear to be an anomalous trichromatic and the other colour blind. I find that a colour blind person (a dichromic with considerable shortening of the red end of the spectrum) may make a match like a normal sighted one. F. W. EDRIDGE-GREEN.

St. John's College, Cambridge.

MEETING OF THE BRITISH ASSOCIATION IN SOUTH AFRICA.

THE arrangements for the forthcoming meeting of the British Association in South Africa have now been completed, and Mr. Silva White, the assistant secretary of the association, sailed for Cape Town in the *Walmer Castle* on Saturday last, July 1. The number of members who will proceed to South Africa to attend the meeting is 385, and of these no less than 276 members have intimated their intention to visit the Victoria Falls at the conclusion of the ordinary work of the association. The official party, consisting of leading representatives of science and guests of the association, with the general and sectional officers for this meeting and the president, numbers 140 in all, and will sail by the *Saxon* on July 29. Most of the other members will proceed to the meeting by the *Durham Castle* and the *Kildonan Castle*, both of which sail on July 22.

In a previous article (May 18, p. 59) the local arrangements for the meeting were described. There will be receptions and social functions, excursions, &c., at Cape Town, Durban, Pietermaritzburg, Johannesburg, Kimberley, and Bulawayo. The central organising committee for South Africa (chairman, Sir David Gill, K.C.B., F.R.S., hon. secretary, Dr. Gilchrist) has carried out the coordinating work of the programme. The lists of local committees and subcommittees contain nearly one thousand names, from which it may be concluded that much interest is taken in the meeting.

As already mentioned, lectures of a popular character will be delivered at the chief towns visited. These lectures have now been definitely arranged as follows:—

Cape Town: W. J. Burchell's discoveries in South Africa, Prof. Poulton; some surface actions of fluids, Mr. C. V. Boys. *Durban:* Mountains: the highest Himalaya, Mr. D. Freshfield. *Pietermaritzburg:* Sleeping-sickness, Colonel D. Bruce. *Johannesburg:* Distribution of power, Prof. Ayrton; steel as an igneous rock, Prof. Arnold. *Pretoria:* Fly-borne diseases, malaria, sleeping-sickness, &c., Mr. A. E. Shipley. *Bloemfontein:* The Milky Way and the clouds of Magellan, Mr. A. R. Hinks. *Kimberley:* Diamonds, Sir William Crookes; bearing of engineering on mining, Prof. Porter. *Bulawayo:* Zimbabwe, Mr. Randall-MacIver.

The president's address to the association will be delivered at Cape Town on August 15, and at Johannesburg on August 30. Mr. G. W. Lamplugh's report on the geology of the Victoria Falls will take the form of an afternoon address to Section C at Johannesburg.

Subjoined is a draft programme of the work of the sections:—

Section A (Mathematics and Physics).—*Cape Town:* President's address; progress of the arc of meridian and geodetic survey of South Africa, Sir D. Gill; to what extent can the ether affect the motion of matter? Prof. J. Larmor; observations of atmospheric electricity in South Africa, Prof. Beattie and Mr. Lyle; leak of electricity from certain heated substances, Prof. Beattie; the foundations of the kinetic theory of gases, Mr. Burbury; application of the kinetic theory of nebulæ, Mr. J. H. Jeans; radiation at low temperatures, Dr. J. T. Bottomley. There will also probably be communications from Mr. Hough on tides, and from Dr. Roberts on the Algol variables. *Johannesburg:* On the teaching of elementary mechanics (jointly with Section L if possible), Prof. J. Perry; on flight, Prof. G. H. Bryan; (1) electrical conductivity in relation to chemical action; (2) magnetic survey of South Africa, Prof. Beattie; report of the seismological committee, Prof. J. Milne; a form of dry Daniell cell, Mr. J. Brown; the strength of winding ropes in mines, Prof. Perry; the experimental foundations of the theory of heat conduction, Dr. C. H. Lees. There will probably be a communication from Mr. Sutton on the meteorology of South Africa.

Section B (Chemistry).—Detailed information regarding papers offered by members in South Africa has not yet been received, but the following provisional arrangement has been made:—*Cape Town:* Recent advances in agricultural science, A. D. Hall; vegetable assimilation, Dr. Horace T. Brown; enzyme action, Dr. E. F. Armstrong. These communications are intended to serve as a basis of discussion of agricultural chemical problems. *Johannesburg:* President's address; reports on various aspects of the metallurgy of gold by local experts. Communications by Dr. H. Marshall on the experimental basis of the dissociation hypothesis, and by H. Ingle on the soils of the Transvaal, have been provisionally accepted.

Section C (Geology).—*Cape Town:* Opening remarks by the president; the continent of Africa in relation to the physical history of the earth, Prof. W. J. Sollas; the classification of the Karroo beds of South Africa, Prof. R. Broom; report of the committee on the fauna and flora

of the English Trias, J. Lomas; extraordinary daily fluctuations in a Karroo well, Prof. A. Young; and other papers on the Karroo or Trias. *Joint meeting with Section E (Geography)*.—The physical geography of Cape Colony, H. C. Schunke-Holloway; Glacial periods in South Africa, A. W. Rogers; changes of climate, as shown by movements of the snow line and upper tree line since Tertiary times, Prof. A. Penck; physiographical subject, Prof. W. M. Davis; Baviaan's Kloof, a contribution to the theory of mountain folds, E. H. L. Schwarz; the Stormberg formation in the Cape Colony, A. L. Du Toit; on the geology of South Victoria Land, H. T. Ferrar. *Johannesburg:* President's address; magnetic segregation of sulphide ores, Dr. A. P. Coleman; marginal phenomena of granite domes, Prof. G. A. J. Cole; relation of the igneous rocks to the crystalline schists, F. P. Mennell; the indicators of the goldfield of Ballarat, Prof. J. W. Gregory; petrographical subject, Prof. R. B. Young; the diamond pipes and fissures of South Africa, H. S. Harger; recent work of the Transvaal Geological Survey, H. Kynaston; the Victoria Falls, G. W. Lamplugh; the great laccolitic intrusions of the Bushveld, Dr. G. A. F. Molengraaff; evidences in the Transvaal of Glacial conditions in permo-Carboniferous times, E. T. Mellor; geological notes on the excursion to Pretoria, A. L. Hall; the great West Rand upthrust, Dr. J. T. Carrick; notes on a sedimentary formation older than the Witwatersrand beds, E. Jorissen; interesting outlines of the Witwatersrand formation, Dr. J. T. Carrick.

Section D (Zoology).—*Cape Town:* President's address; the Triassic reptiles of South Africa, with remarks on the origin of mammals, Dr. Broom; a comparison of the Permian reptiles of Russia with those of South Africa, Prof. Amalitzky; South African scorpions, Dr. Purcell; recent work on gametogenesis and its bearing on theories of heredity, L. Doncaster; the migration of birds in the southern hemisphere, W. L. Sclater; the ostrich, A. H. Evans. *Johannesburg:* Pearl oysters and pearls, Prof. Herdman; recent discoveries in the South African deep sea, Dr. Gilchrist; cephalodiscus, Dr. Harmer; the growing-point in vertebrates, Prof. Cleland; South African ticks, Drs. Cooper-Foster and Nuttall.

Section E (Geography).—*Cape Town:* President's address; afforestation of South Africa; the unveiling of the coasts of Africa (lantern views of old maps), H. Yule Oldham; the Ordnance Survey of the United Kingdom, Colonel Johnston; a comparison of the periodicity of the meteorological conditions of London and Cape Town, Dr. H. R. Mill; Gough Island, Rudmose Brown; terrestrial globes as a necessary adjunct to the teaching of geography, Captain Creak; excursions as a means of teaching geography (lantern), J. Lomas. *Johannesburg:* The evolution of Africa, Dr. J. Scott Keltie; a new rainfall map of Africa, A. J. Herbertson and P. C. Waite; boundaries and areas in Africa, J. Bolton; the physical geography of the Transvaal, Tudor Trevor; notes on the geography of Africa south of the Limpopo, F. S. Watermeyer; the game preserves of the Transvaal, Major Stevenson Hamilton, D.S.O.; the Sikhim Himalayas and Tibet, Douglas W. Freshfield; Asiatic subject, Prof. Cordier.

Section G (Engineering).—*Cape Town:* Metcalfe on Zambezi Bridge and Rhodesian railways; ocean turbine boats, Prof. Byles; roller bearings, wire ropes in mines, and probably automobiles. *Johannesburg:* President's address (irrigation); strength of winding ropes in mines, Prof. Perry.

Section H (Anthropology).—*Cape Town:* President's address; the totemism of the Bantu, E. S. Hartland; the musical instruments of the natives of South Africa, Hy. Balfour; American Negroes, Miss Pullen-Burry; artificial deformation in Africa, Dr. von Luschan. *Johannesburg:* arts and crafts among the natives of South Africa, Dr. Schoenland; stone implements in South Africa, Mr. Johnstone; bushman paintings with reproductions, Dr. Squire; the affinities of the Hottentots, Dr. von Luschan; the Modjadje, Rev. Reuter; the Bawenda, Rev. Gottschling; report on Zimbabwe, Mr. MacIver; the Basuto, H. E. Mabille.

Section I (Physiology).—*Cape Town:* Discussion on the effect of climate on health, opened by Sir T. Lauder Brunton (Dr. David Ferrier, Prof. McKendrick, Dr. Gregory, Dr. Jasper Anderson, Prof. Bohr, and Dr. J. A. Mitchell will take part); so-called scurvy of South Africa, Dr. Gregory; on plague, Dr. J. A. Mitchell; leprosy in Cape Colony, Dr. A. S. Black; South African drugs, Dr. Moberley; discussion on horse-sickness and allied diseases, opened by Dr. Edington (Dr. Hutcheon, Mr. du Plessis, Dr. Wm. Robertson, Colonel Bruce, and Prof. Sims Woodhead will take part); stock diseases in South Africa, Dr. Hutcheon; ticks as a means of conveying disease in South Africa, Mr. Lounsbury. *Johannesburg:* President's address; horse-sickness, Dr. Theiler; rinderpest, Dr. G. Turner; a discussion on lung diseases in connection with mining (Dr. Sims Woodhead) is under consideration; nervous diseases, Prof. Ferrier; the life-history of coloured labourers in the Transvaal, Dr. D. Macaulay and Dr. Louis Irvine; dysentery, Colonel Cecil Birt.

Section K (Botany).—*Cape Town:* The present position of our knowledge of seaweeds, Prof. R. W. Phillips; the fossil floras of South Africa, A. C. Seward; educational methods in the teaching of botany, Harold Wager; notes on irrigation farming on the Orange River, F. B. Parkinson. *Johannesburg:* President's address; photography as an aid to œcological research, Prof. F. E. Weiss; the problems of heredity, R. P. Gregory. It is expected that Prof. Engler, Prof. Pearson, and others will contribute papers.

Section L (Educational Science).—*Cape Town:* President's address; the teaching of science, Prof. H. E. Armstrong; the teaching of science in South Africa, Dr. Hahn; rural education, appropriate to colonial life in South Africa, and agriculture, A. D. Hall; the higher education of women in South Africa, Miss Clark; disabilities of South African school boys, W. A. Way; Cape education, its difficulties and development, Rev. W. E. C. Clarke. *Johannesburg:* Changes in the Dutch language since its introduction into South Africa, Dr. Brill; education on the veldt, Mr. Corbett; prospects of secondary schools in the Transvaal, Mr. Hope; teaching of agriculture, F. B. Smith; native education, Hobart Houghton; progress of education in the Transvaal, H. Warre Cornish; education in Rhodesia, G. Duthie; a school of forestry, T. R. Simms; the teaching of architecture, R. G. Kirkby; education in the Orange River Colony, Hugh Gunn; manual instruction in the Transvaal, T. Lowden; recent improvements in the training of infants, with special reference to South Africa, Miss Welldon; discussion with Section A, the teaching of elementary mathematics.

THE PRINCIPLES OF GEOLOGY.[1]

THE principles are, notwithstanding the origin of the word, the last things you attain to in the course of scientific investigation; but they are what you first explain to another who is commencing his study. You may make a further selection of such parts as are for any reason the easiest or most suitable for him to begin with, and call them the elements. Lyell's classic work has pretty well fixed what shall be the conventional meaning of "The Principles of Geology." They are the laws or explanations which we arrive at in respect of the phenomena exhibited in the earth's crust from direct observation of those phenomena themselves or of the recent operations of nature which we see producing analogous results. Their value depends upon the opportunities afforded of obtaining evidence and upon the personal faculty of eliminating sources of error.

In the case of geology, the subject is so vast that its different branches are growing further and further apart, until they seem to have an intergrowth with the branches from other subjects the original stem of which was far removed from their own.

From the observation of rock masses inferences have been drawn as to the conditions which prevailed in past times, and theories have been propounded as

[1] "Structural and Field Geology." By Dr. Jas. Geikie. Pp. xx + 435. (Edinburgh: Oliver and Boyd; London: Gurney and Jackson, 1905.) Price 12s. 6d. net.

to the forces which have rolled up the strata and produced such varied superficial and deep-seated phenomena. These form the principles of dynamical geology, and it is the description of the resultant structures and the methods of observation which form the chief subject of the interesting handbook just published by Dr. James Geikie under the title "Structural and Field Geology."

The two first chapters are devoted to an examination of the rock-forming minerals. These are very few in number if we leave out all except those which are the essential constituents of the common rocks.

After studying their composition and characteristics in hand specimens or small slices adapted for examination under the microscope, there is much to be learnt as to the history of the earth's crust from the observation of large masses of rock. We can see whether they were laid down in comparatively tranquil water, or hurled along by torrents, or dashed against a shore. We notice that what was once mud or sand or shingle is now solid rock, and we try to make out in each case whether this was brought about by the introduction of some cementing material or caused by the pressure of superincumbent masses, and whether the changes were helped by the action of the high temperature experienced by rocks depressed to great depths or crushed by irresistible earth movements. Chemical reactions and the crystallisation of various minerals out of the material of the rock produce changes on a small scale, as seen in concretions and drusy cavities, or on a large scale as in the case of the formation of vast beds of crystalline limestone from the calcareous fragments of various organisms. We can infer from a comparison of certain rocks with the products of recent volcanoes that ancient volcanoes also injected molten matter through the riven rocks, poured out vast sheets of lava, and covered wide areas with volcanic ash.

Fig. 1.—Fault-rock, River Garry, at Dalnacardoch, Perthshire. (Reproduced on a reduced scale from "Structural and Field Geology," J. Geikie.)

The rocks so formed and so altered have yet to be regarded from another point of view. They have been depressed, uplifted, and thrown into all sorts of positions, now being dragged out, now crumpled up into every variety of fold, the compressible portions often making up by vertical thickening what they lose in horizontal extent, and those that would not yield to such molecular re-arrangement being reduced to the same dimensions by crumpling.

Divisional planes are developed in them, some being due to crush, some to shrinkage, some to the variety in the succession of deposits, and when the strained and bending rock must break it is apt to give along these lines of weakness, so that we find faults commonly coinciding with master joints, thrusts with bedding planes, and so on.

The last seven chapters are more specially devoted to the second subject in the title of the book, namely, field geology. This could not be altogether dissociated from the observations recorded in the earlier part of the work. The information there given is the outcome of original observations in the field, but our author now deals more with the methods employed, and explains what are the most useful appliances for the work and what are the indications which the surveyor must be on the alert to detect. Perhaps, having regard to the numerous monographs which have recently been published on the subject of scenery, he has given greater prominence to the causes than to the effects, to the earth structures to which most scenic features must ultimately be referred rather than to the total result of movement and denudation by which anomalous river flows and abnormal features must be explained.

A study of recent organisms enables us sometimes to establish the relation between the soft and perishable parts and the hard parts which alone are commonly preserved in the rocks, and thus by a comparison of the fossil forms with their nearest recent representatives to learn something of the order of succession of life upon the earth and the conditions under which fossil plants and animals existed. Such analogies must not, however, be pressed too hard. Even such a recent case as the occurrence together of the remains of lion, hyæna, and hippopotamus with the hairy elephant and woolly rhinoceros in our gravel terraces can hardly yet be said to have received an altogether satisfactory explanation. Before we draw inferences from the abundance or rarity of certain fossil organisms we must carefully consider their mode of entombment and the conditions which favour the preservation or the destruction of their remains.

Dr. Geikie has dealt very shortly with these principles of palæontology, but devotes most of his work to the inorganic side of geology.

Even with this limitation of subject the work takes a somewhat encyclopædic character owing to the great number and variety of the observations and inferences which have to be recorded. The treatment is rather dogmatic than critical. With an author so experienced and acute in observation this may be for many an advantage, but students require a discussion of arguments where conclusions differ, and references to other authors where they may find the matters more fully treated which are here of necessity briefly stated.

The formation of ripple marks, for instance, wants fuller explanation than the statement that "they owe their origin to a wave-like motion set up in the semifluid sediment by the water passing over it."

The work is illustrated by a large number of diagrammatic sketches by the author and photographs by members of the staff of the Geological Survey. As examples, we reproduce the pictures of two common phenomena which have many points of general resemblance to one another but a very different origin. Plate xxxix. represents a fissure the strata on either side of which have been relatively displaced by earth movements, either repeatedly in one direction or with a to-and-fro motion, so that the walls of the fissure have been rubbed smooth, fluted, and polished by the movement. The triturated rock and the fragments broken off fill the crack, and this débris is often penetrated by mineral matter and consolidated into a mass harder than the rocks through which it passes. The walls of the fissure are sometimes altered mechanically and by infiltering water to a considerable depth.

In Plate xliv., on the other hand, we see a rift in the rocks filled with matter which has welled up from deep-seated rock which has become molten. In this case, also, the immediately adjoining portion of the rock which it traverses is altered, and very commonly shows slickensides when earth movements have acted upon these two rocks of such different tenacity and hardness; but the composition of the traversing rocks is so unlike in the two cases, and the character of the marginal alterations so dissimilar, that there is seldom any room for doubt as to the origin of each.

Our author has wisely avoided most of the shibboleths which it is the fashion for specialists to introduce into their explanations of the simplest phenomena, but though students may escape the interruption of having to consider the exact application of mylonisation and schillerisation, which are not in the index, though one is found in the text, they must learn the meaning of such terms as synclinorium or geanticline. Difficulties and absurdities in nomenclature are perhaps characteristic of the present phase of scientific literature, and our author has been wonderfully considerate in this matter, and has given us a very useful handbook, admirable in the freshness and terseness of its descriptions and the clearness and abundance of its illustrations.

Fig. 2.—Basalt Dyke Cutting Sandstone and Shale, Kilbride Bennan, Arran. (From "Structural and Field Geology," J. Geikie.)

NOTES.

AMONG those who are the recipients of the King's birthday honours we notice the following:—Lord Rayleigh, O.M., F.R.S., has been made a Privy Councillor; Knighthoods have been conferred upon Prof. T. McCall Anderson, of the University of Glasgow; Mr. E. W. Brabrook, C.B., formerly Registrar of Friendly Societies; Dr. A. B. W. Kennedy, F.R.S., Emeritus professor of engineering and mechanical technology at University College, London, and president of the Admiralty Committee on Machinery Designs; Dr. Boverton Redwood; and Dr. W. J. Smyly, president of the Royal College of Physicians, Ireland. Colonel D. Bruce, F.R.S., has been made a Knight Commander of the Bath. Dr. W. T. Prout, principal medical officer, colony of Sierra Leone, and Dr. J. W. Robertson, late Commissioner of Agriculture and Dairying of the Dominion of Canada, have been made C.M.G.'s. The

honour of Knight Bachelor has been conferred upon Dr. E. S. Stevenson, member of the medical council of the Cape of Good Hope; and Mr. Philip Watts, F.R.S., Director of Naval Construction, is made an ordinary member of the Civil Division of the Second Division, or Knight Commander, of the Order of the Bath.

A meeting of Members of Parliament, presided over by Mr. Haldane, met on Tuesday last in a committee room of the House of Commons to consider the question of a request for an additional State grant to the National Physical Laboratory. Dr. Glazebrook having made a statement as to the aims and needs of the laboratory, was followed by Mr. Chamberlain, who in the course of his remarks said that the real problem of the nation was how to improve our highest education. He felt convinced that if they were to speak of the whole matter as an investment, it was from higher education that they would gain the largest return. He asked in what way the National Physical Laboratory was distinct from other universities, such as those of Birmingham, Liverpool, Manchester, and Sheffield. He asked this because it was not merely the object of the universities to educate young persons; it was their object to carry on post-graduate research in the largest possible way—to make precisely the experiments which the laboratory was making. They did not want in any way to discourage that work in these separate universities; they did not want to centralise any branch of scientific work. He had himself rather a horror of central institutions, and he had a great belief in the freedom and the competition of a number of separate centres. He was sure that there was no idea of injurious competition in the minds of the promoters of the meeting; but he would like to be certain that it might not have that effect. After all, they were all more or less dependent, and they would be increasingly dependent, upon State aid, of which they had had very little up to the present. Were the universities, each of them, to apply separately and frighten the Treasury, or were they to put their forces together, and go as one body representing the whole and ask for a very largely increased grant, leaving it for consideration afterwards how that grant should be divided? Why were they making a special demand at that time for that particular institution? He was all in favour of giving assistance to any institution of the kind. But he should like to know in what way this was to be distinguished from the University of Liverpool or any of the others where they were carrying on the work of physical research. He would even ask why the promoters of this institution should operate alone—whether they would not do much more if they all came together. In that case they would, of course, have very much larger Parliamentary support. If each institution was to ask for what it wanted he was afraid the chances of success would not be great. He might be considered to be throwing cold water on the matter at the beginning, but as a fact he most entirely sympathised with the general object. He thought that such an institution was absolutely necessary, and if there were no others, then he would say most distinctly that it would have a special claim upon them. But as there were, and as they were all in their infancy, he wished to know in what way it was thought best to treat the matter when they approached the Government, whether as a whole on behalf of scientific instruction generally or whether on behalf of the claims of that particular institution. The chairman said they were all interested in what Mr. Chamberlain had said, and his suggestion of a collective movement in favour of the highest education. He thought the work that the National Physical Laboratory was doing could not be organised in connection with any of the universities. The following resolution was then put to the meeting and carried unanimously:—"That this meeting, being satisfied of the necessity of further State aid to the National Physical Laboratory, at Teddington, as regards both equipment and maintenance, requests the chairman and conveners of this meeting to prepare and present a memorial to the Chancellor of the Exchequer asking for such additional aid, and that the memorial be signed by members here present or who, being absent, may be in sympathy with its objects." Mr. Chamberlain, who had to leave before a decision was arrived at, said that if the meeting decided in favour of the resolution his name might be attached to it.

On Monday last Mr. Ailwyn Fellowes, President of the Board of Agriculture, was waited upon by a deputation from the Pharmaceutical Society respecting the proposed legislation to extend to other than chemists the right of selling poisonous products used in agriculture and horticulture. It was argued on behalf of the society that it would be dangerous to the public to allow any one to sell poisonous articles; that there was no difficulty in the way of farmers or horticulturists getting the articles through a chemist as cheaply as through any other person; and the public would be safeguarded by the special knowledge of the chemist and druggist. In reply, the President of the Board of Agriculture said he had received an enormous number of resolutions from all over the country in favour of a relaxation of the present law. The new regulations under the proposed Bill would provide:—(1) that no poisonous substance shall be kept in any shop or premises where articles of food are stored or kept for sale; (2) that poisons must be kept in a separate cupboard from other goods; (3) all poisons shall be sold in an enclosed vessel, labelled with the word "Poison"; (4) liquid poisons shall be sold only in bottles or tins easily distinguishable by touch from ordinary bottles or tins; (5) in granting licences the local authority shall have regard to the facilities already existing in the neighbourhood for the purchase of poisonous compounds.

According to the Berlin correspondent of the *Daily Chronicle*, Dr. Robert Koch has written from German East Africa stating that he has been studying the nature, habits, and anatomy of the tsetse fly, and that he has discovered a certain parasite in the fly to which he attributes the disease to which the cattle bitten by the fly succumb.

The death is announced, at the age of fifty-five years, of Prof. von Mikulicz-Radecki, of the University of Breslau, well known as a surgeon and for his numerous papers and memoirs on surgical subjects. About a year ago he delivered the Cavendish lecture before the West London Medico-chirurgical Society, and last year he was the president of the surgical section of the German Association of Men of Science and Medical Men.

The death is announced of Prof. P. T. Cleve, of Upsala, on June 18. He was born in 1840, and was the leading exponent of chemical research in Sweden. His hydrographical investigations were also of great importance. He was an honorary member of the Chemical Society.

The Barnard medal of Columbia University has just been awarded to Prof. H. Becquerel for "important discoveries in the field of radio-activity, and for his original discovery of the so-called dark rays from uranium, which discovery has been the basis of subsequent research into

the laws of radio-activity, and of our present knowledge of the same." The medal has been previously awarded to Lord Rayleigh, Sir William Ramsay, and Prof. Röntgen.

A PORTRAIT of Prof. W. Osler has been presented to the University of Pennsylvania by the members of the classes which from 1885 to 1891 studied under Prof. Osler when he occupied the chair of clinical medicine at the university.

A MEDAL has been struck to commemorate the successful completion of the Simplon Tunnel. On one side of the medal is a figure of Mercury and a locomotive emerging from the tunnel, with the inscription "Aux Collaborateurs et Ouvriérs du Percement du Simplon"; on the other is a representation of the meeting of the workmen when the last obstacle had been broken down, and bears the words "Souvenir de la Rencontre des Galeries, Fevr. 1905."

BUSTS of Joseph Lancaster and Michael Faraday—the gift of Mr. Passmore Edwards—were unveiled on Wednesday of last week in the entrance hall of the Borough Polytechnic Institute by Prof. Silvanus P. Thompson, F.R.S., who delivered an address.

To commemorate the anniversary of the one hundred and twenty-fifth birthday of Audubon, the American Museum of Natural History has placed on exhibition a collection of Audubon relics, among which is the portfolio in which Audubon carried specimen plates while securing subscribers to his great work, together with sketches and finished plates.

A SCHEME for the establishment of a Central Research Institute at Kasauli, and a laboratory for scientific, medical, and sanitary work at the headquarters of each provincial Indian Government, to provide more adequate means for the scientific study of etiology and the nature of the diseases of the country, has been published. It is hoped that when the project has been developed, not only will it be no longer necessary for officers to go to Europe to study the bacteriology and parasitology of tropical diseases, but that workers from England and the European Continent will avail themselves of the Indian laboratories and the unrivalled material for study which the diseases of the country afford. The scheme has the approval of the Secretary of State, and the Government of India proposes to appoint as the first director of the Central Research Institute Lieut.-Colonel Semple, M.D., well known for his work in connection with the Pasteur Institute of India.

A NEW society, to be known as the Harvey Society, has been established in New York under the patronage of the New York Academy of Medicine. Its purpose is the diffusion of scientific knowledge of anatomy, physiology, bacteriology, pathology, pharmacology, and physiological and pathological chemistry by public lectures given by men who are workers in the subjects presented. Each lecture is intended to represent the state of modern knowledge concerning the topic treated, and will be addressed to the general medical profession who are interested in the scientific side of medicine. The president is Dr. Graham Lusk. The members of the society consist of two classes, active and associate members. Active members are laboratory workers in the medical sciences residing in New York; associate members are such persons as may be in sympathy with the objects of the society, and reside in New York. The first course of lectures will be given at the Academy of Medicine on Saturday evenings during the winter of the years 1905–6.

A CONVERSAZIONE took place at King's College, London, on Thursday last, when many scientific and other exhibits were on view. An interesting item was a set of various forms of glow-lamps, a demonstration of which was given by Prof. E. Wilson in the Siemens electrical engineering laboratory, and which included mercury-vapour, Nernst, tantalum, and osmium lamps. There was also an exhibition of crystallisation shown on the screen by Prof. Herbert Jackson.

THE annual conversazione of the Institution of Electrical Engineers was held on June 29 at the British Museum (Natural History), South Kensington. It was attended by upwards of 1000 guests.

THE third International Electric Tramway and Railway Exhibition was opened at the Agricultural Hall, Islington, on Monday last by Lord Derby.

THE annual general meeting of the Society of Chemical Industry will begin in London on Monday next, June 10. The society numbers among its members some 1500 Americans, and at the last annual meeting, which, with special reference to the St. Louis Exhibition, was held in the United States, an American, Dr. W. H. Nichols, was elected president in succession to Sir William Ramsay. The American visit was a great success, and the British members of the society have looked forward to the time when they would be able to welcome in Great Britain their president and American and Canadian co-members. The proceedings in connection with the forthcoming meeting have therefore been specially arranged in view of this return visit. Dr. Nichols has already arrived in England, and we understand that the guests of the society will number in all about 120. A lengthy and interesting programme has been arranged.

THE sixty-fourth annual meeting of the Medico-psychological Association of Great Briain and Ireland will be held at 11 Chandos Street, Cavendish Square, on July 20 and 21 under the presidency of Dr. T. Outterson Wood. The annual dinner of the association is to take place on July 30 at the Whitehall Rooms.

THE American Anthropological Association is to meet in San Francisco, Cal., from August 29 to 31 next under the presidency of Prof. F. W. Putnam, when papers relating to ethnology, archæology, prehistoric man, physical anthropology, linguistics, and general anthropology will be read. The museum of the department of anthropology of the University of California at the affiliated colleges in San Francisco, which has recently been installed, but not yet opened to the public, will be the headquarters of the association.

A PRELIMINARY circular has been issued to announce that the tenth International Geological Conference will be held in 1906 in Mexico. An executive committee has been appointed, with M. José G. Aguilera, director of the National Geological Institute of Mexico, as president, and M. Ezequiel Ordóñez, assistant director of the same institution, general secretary. It is expected that the congress will open on September 6, 1906, and last for eight days.

THE Postmaster-General again directs attention to the fact that pathological specimens and articles of a similar nature may be forwarded only by registered letter post and in proper cases. The Post Office regulations provide that any deleterious liquid or substance sent by post must be enclosed in a receptacle hermetically sealed, which receptacle must itself be placed in a strong wooden, leathern,

or metal case, in such a way that it cannot shift about, and with a sufficient quantity of some absorbent material (such as sawdust or cotton wool) so packed about the receptacle as absolutely to prevent any possible leakage from the packet in the event of damage to the receptacle. The packet must also be marked "Fragile with care."

An exhibition of the results obtained last year by Prof. Flinders Petrie and his coadjutors in the field of Egyptian archæology was opened at University College, Gower Street, on Thursday last, and will remain on view for a month. Last winter excavations were carried on in the peninsula of Sinai. At Sarabit el Khadem the mines were of turquoise, and no copper was found. The interesting feature on this site is the evidence of the Semitic—not Egyptian—worship which was practised. The whole region is scattered over with shelters for pilgrims, usually containing a Bethel stone, some of which have Egyptian inscriptions of the twelfth dynasty. The pilgrims came for oracular dreams like Jacob's, and the shelters are only in the region of the temple. They are quite distinct from the miners' dwellings, such as are common at Wady Maghara. This Bethel custom is a special feature of Semitic belief, and is quite unknown in Egypt. The temple at Sarabit was originally a sacred cave—perhaps as early as Seneferu. It was carved by Amenemhat III., and furnished with altars for the worship of Hathor. In front of it, on the edge of the hill, was an enormous mass of ashes of burnt offerings, showing the burnt sacrifices on high places familiar to Semitic worship. The temple was extended over these burnt offerings by Tahutmes III. and other kings until Sety I. Of the temple itself a beautiful and instructive model is shown, the scale being one-fiftieth. The whole length of the building is nearly 250 feet. Though it has been known since the time of Niebuhr, no clearance had been made; but now many new features have been brought to light from under the rubbish. The primitive shrine of Hathor was a rock cave, and the discovery of a hawk with the finely cut name of Seneferu makes it probable that the shrine is as old as the third dynasty.

It is announced in the *Electrician* that as a result of the successful experiments with the De Forest wireless telegraphy in moving trains, the Chicago and Alton Railway will supply wireless telegraphy apparatus on its two express trains running daily between Chicago and St. Louis, and ultimately on its whole system. Messages were received while the train was running at fifty miles per hour. For some time while the train was approaching the Mississippi River above the elevated stretch leading to Merchants' Bridge, the increase in strength of the signals was very marked, but when the train entered the framework of the bridge it was found that signals became almost imperceptible owing to the screening action of the bridge. It was observed also that the signals were stronger when the train was broadside on to the transmitting station and running at right angles to it. The fact that the radiations were following the course of the river in preference to overland paths was very marked as the train pulled out of Alton, Illinois. At one point the track runs within a few hundred feet of the river, and at this point the signals from St. Louis, thirty miles away, which had just previously become very weak, were increased in intensity to a surprising degree. No difficulty seems to have been experienced even when the train was many miles from the transmitting station and was threading through the yards and sidings of Chicago, completely hidden by large elevators and steel structures of every description.

The New York correspondent of the *Lancet* states that a subcommittee of twenty-one coloured physicians and clergymen has been organised by the New York Charity Organisation Society's Committee on the Prevention of Tuberculosis to fight tuberculosis among the coloured people of New York. The New York health board is cooperating with the movement, and has placed its dispensary under the supervision of the medical members of the subcommittee for three evenings a week. A course of illustrated lectures treating of tuberculosis will be given shortly in the churches for coloured congregations. It is stated that there are between 60,000 and 65,000 coloured persons in New York city, and that their death-rate from tuberculosis is 5·33 per 1000, as against 2·37 per 1000 among the whites.

The first part of the Home Office "Mines and Quarries: General Report and Statistics for 1904" has just been issued. The total number of persons employed at the mines of the United Kingdom was 877,057, of whom 847,553 worked at the 3333 mines under the Coal Mines Act and 29,504 at the 673 mines under the Metalliferous Mines Act. The total number at coal mines is the highest recorded since 1873, and that at metalliferous mines the lowest. The output included 232,428,272 tons of coal, 3,043,045 tons of fireclay, 7,557,733 tons of ironstone, and 2,333,062 tons of oil shale. The coal production is the highest recorded. The deaths from accidents amounted to 1055 in collieries and 35 in metalliferous mines, the death rate per 1000 persons employed being 1·24 in the former case and 1·19 in the latter. It is gratifying to note that the former rate has never been lower.

No. 21 of the *Publications of the Earthquake Investigation Committee* (Tokyo) contains a lengthy paper by Prof. Omori on horizontal pendulum observations at Tokyo; the most interesting of the results is the conclusion that the first movement is usually towards the origin in the case of near or moderately distant earthquakes, but in a small proportion of the records it is away from the origin. The author attributes this difference to a distinction in the cause of the earthquakes, the first type being due to the sudden collapse of a subterranean cavity, or the crushing down of a horizontal stratum, and the second type to the sudden splitting asunder or widening of a vertical cavity by the expansive action of steam or gases. In another part of the paper, however, he points out that in the case of artificial earthquakes caused by explosions, the first movement is outwards if these take place on the surface of the ground, but inwards if the explosive is buried at some little depth. Other points which are commented on are the resemblance between the records of earthquakes of similar intensity and originating in the same region, and the occasional occurrence of long-period undulations combined with shorter-period vibrations in the first phase of distant earthquakes.

The investigations of the relation between variation of barometric pressure and sea level on the coast of Japan, which were noticed in Nature of November 3, 1904, has been continued by Prof. Omori, who shows, in the *Proceedings of the Tokyo Physicomathematical Society* (vol. ii., No. 20), that the relationship found on the Pacific extends to the western coasts of Japan, so that all round these islands the rise of sea-level is greater than that due to the local diminution of barometric pressure alone. The consequence of this is that a low barometer means a

decrease of pressure on land but an increase of pressure on the surrounding sea bottom, the latter being about 1·6 times as great as the former. An interesting result, attributed to this cause, is given in No. 21 of the *Publications of the Earthquake Investigation Committee*, where the behaviour of a horizontal pendulum during the storm of October 10–11, 1904, is described; the low-pressure area passed to the east of Tokyo, and during its passage the horizontal pendulum indicated a tilting, which reached 3·5 seconds of arc, to the east—that is, in the direction of the low barometric pressure—indicating an increase of pressure on the sea bottom in that direction.

WE have received the report of the Government Observatory, Bombay, for the year 1904. This observatory deals chiefly with terrestrial magnetism, meteorology, and seismology; it has issued a long series of valuable publications, and many years ago Mr. Charles Chambers, then director, prepared an elaborate discussion of the meteorology of Bombay. The care bestowed upon the records of the photographic self-registering instruments may be gathered from the fact that the watchmen go round once every hour, night and day, to see that the clocks are all going and the lights burning. Their regular attendance is automatically recorded on the photograms themselves. The total rainfall for the year amounted to only 33·4 inches, being 41·7 inches below the normal value for twenty-four years (1873–96); this is the smallest fall recorded at the observatory. Milne's seismograph registered thirty-five earthquakes during the year.

FROM information received from the president of the International Aëronautical Committee, we find that in the months of January to April last the average monthly number of stations participating in the balloon and kite ascents was sixteen; kite observations were made each month at Oxshott by Mr. Dines, and at Aldershot, by the military balloon section, in February and March. The most notable heights attained, by means of unmanned balloons, were 19,420 metres at Strassburg and 21,733 metres at Berlin. In April kite and unmanned balloon observations were made from the Prince of Monaco's yacht in the Mediterranean. These are the first ascents made with unmanned balloons in the open sea, and these successful experiments show that Prof. Hergesell's idea of obtaining such observations over the oceans may possibly be realised.

BULLETIN No. 35 of the Storrs Agricultural Experiment Station, Conn., deals with the Camembert type of soft cheese. The conclusion is arrived at that the ripening is due to definite moulds and bacteria. One mould (? *Penicillium candidum*) seems to produce the changes which result in the texture of the cheese, and it, together with the *Oidium lactis*, produces the flavour, lactic acid bacteria giving the necessary acidity and retarding the action of other bacteria. It is found possible so to control the process of ripening that the desired result may be obtained with reasonable uniformity.

WE have received the first number of a new periodical, the *Medico-technologisches Journal*, edited by Dr. Berthold Beer, which is to be devoted to medical and surgical instruments and the various apparatus employed in bacteriology, photography, radiography, hygiene, &c., and appertaining to the medical sciences and physical therapeutics. It contains a prefatory article by Dr. Beer, and descriptions of Zeiss's apparatus for the demonstration of ultra-microscopic particles and of various surgical instruments and pharmaceutical preparations, together with photographic and balneological notes and new literature. Such a journal, provided it gives concise descriptions of the principal new inventions of the various countries, and not of Germany only, should supply a decided want.

IN a paper contributed to the June number of the *Zoologist* Mr. J. G. Millais points out that the English black rat—the type of *Mus rattus* of Linnæus—is by no means the blackest representative of the species, that distinction falling to a race which it is proposed to call *M. rattus ater*, and of which specimens have been taken in England. No doubt this is right enough, but when the author proceeds to suggest English names for the various local races of the species in question he follows a course which, in our opinion, cannot but land him in difficulties. The species itself he rightly calls the black rat, but for its local races the name of Alexandrine rat is taken, so that the typical form becomes the northern Alexandrine rat, while the new race is termed the black Alexandrine rat. Their proper designations should be the Alexandrine black rat and the Black Sea black rat.

IN the *Transactions of the Royal Society of Edinburgh* (vol. iii., part iii., No. 22) Sir Charles Elliot describes the nudibranch molluscs collected during the Scottish National Antarctic Expedition. These comprise but two species, two of which are, however, referable to new and interesting generic types. The most remarkable feature is the absence in the collection of all representatives of Doris and its allies, a feature common to the *Discovery* collection of this group, which has been entrusted to the author for description. Certain holothurians of the genus Psolus from the Antarctic present a superficial resemblance to dorids, although this is not regarded as more than accidental.

As a supplement to part iii. of Prof. Herdman's report on the pearl oyster fisheries of the Gulf of Manaar, published by the Royal Society, Messrs. Shipley and Hornell describe several new parasitic worms (some referred to new generic types) obtained from elasmobranch fishes frequenting the pearl-banks. Possibly, although not probably, some of the cestodes may be the parent form of the pearl-producing larvæ. No direct light is thrown by the investigations on the problem of the *provenance* of the pearl-producing parasite.

THE departmental committee appointed to investigate certain matters connected with the sea-fisheries of Sutherland and Caithness reports that cod and ling have of late years been much less abundant than formerly on the coast. As regards a proposed close time for herrings, it was considered that the fishermen themselves are the best judges as to whether such a protective measure is advisable. Trawling in the Moray Forth (which is not permitted to British craft) by foreign vessels is held to be responsible for considerable injury to the fishery.

ACCORDING to the report for 1904, the Marine Biological Association of the West of Scotland has had a very successful year, the only drawback being certain difficulties with regard to the staff. The year witnessed the practical completion of the large extensions of the station generously provided by Mr. J. Coats, jun., which were opened by Sir John Primrose in September last, and promise to meet all present requirements. The hope is expressed that it may be found possible to retain the invaluable services of the S.Y. *Mermaid* during the present season.

Nos. 4 and 5 of the admirable series of Cold Spring Harbour Monographs are respectively devoted to the life-history of the chrysomelid beetle *Chlamys plicata*, commonly called "case-bearer," and of the "mud-snail" (dog-whelk), *Nassa plicata*, E. M. Briggs and A. C. Dimon being the respective authors, or, as some would say, authoresses. The case-bearer is remarkable for the fact that its encased larvæ resemble not only undeveloped buds of the alder, but likewise the fruit of the high-vine blackberry. Of the "mud-snail" the life-history and habits are described in considerable detail, and a number of observations recorded with regard to its reactions to light, &c.

Two addresses, on "Spirals" and "Ambidexterity," which were delivered before the Hampstead Scientific Society by Sir Samuel Wilks, Bart., F.R.S., on April 14 and May 12 respectively, have just been issued in pamphlet form by Mr. S. C. Mayle, of Hampstead. The society is to be congratulated on having the active support of so eminent a man as Sir Samuel Wilks.

At the meeting of the Aëronautical Society of Great Britain to be held on Wednesday next, the following communications will be read:—"Some Remarks on Aërial Flight," by G. H. Wenham; "Demonstration of a Bird-like Flying Machine," by Dr. F. W. A. Hutchinson; "Balloon Varnishes and their Defects," by W. F. Reid; and "The Thrust of Aërial Propellers," by W. G. Walker.

OUR ASTRONOMICAL COLUMN.

Observations of the Satellites of Saturn and Uranus.—An important set of observations of the satellites of Saturn and Uranus, involving some hundreds of individual "settings," was made by Messrs. Frederick and Hammond with the 26-inch equatorial of the U.S. Naval Observatory during 1904. The position angle and distance of each satellite were measured from a second satellite, the angle about the inner body always being taken. The observations extended over the period May 24 to October 11, and the detailed results are published in No. 4026 of the *Astronomische Nachrichten*.

Geodetic Measurements from Solar Eclipses.—The *Journal of the British Astronomical Association* (vol. xv., June 22) contains a paper in which Mr. C. E. Stromeyer points out that if the central shadow of the coming August eclipse be accurately located, all the necessary data will be available for the determination of the geocentric difference of any two observation stations. He proposes two methods for eye observations, and two photographic methods, of which one in particular seems capable of being carried out with the desired precision; it consists in photographing a trail of the central phase of the eclipse on to a moving film.

The method described can be carried out both within and outside the shadow, but the best results will be obtained if the observer is just on the edge of the shadow. The method can also be used with annular eclipses, and if found to be trustworthy would be a valuable means for gradually determining the geocentric distances of various points, even of islands in mid-ocean, which can never be triangulated.

Monochromatic Photographs of the Orion Nebula.—On obtaining a series of spectrograms of the Orion nebula with a small objective-prism quartz spectrograph, Prof. Hartmann found that different parts of the nebula emit light of very different composition, whilst large areas, of characteristic forms, shine solely by the ultra-violet radiation at λ 3727. This variety of the light emitted by the several areas of the nebula led Prof. Hartmann to employ colour screens in obtaining direct photographs with a Steinheil reflector of 24 cm. aperture and 90 cm. focal length. Three screens were used; the first completely absorbed all wave-lengths shorter than λ 4800, but allowed Hβ and the two chief nebular lines, N_1 and N_2, to pass through almost without any diminution of intensity. The second screen freely transmitted all radiations between λ 3880 and λ 3740, but absorbed all others, whilst with the third the absorption commenced at λ 5050, increased rapidly to totality at Hβ, extended to λ 4000, and then quickly decreased until at λ 3727 the transparency was very nearly complete. In this screen the two chief nebular lines were faintly transmitted, but it was an easy matter to eliminate their action by employing a plate of suitable sensitiveness. Combining the first and third screens cut out Hβ, leaving only N_1 and N_2 effective.

Marked differences of the intensities of several areas, as shown on the various photographs obtained with different screens, are plainly seen on the reproductions accompanying Prof. Hartmann's paper. Evidently the radiation λ 3727 is extraordinarily intense in *all* parts of the nebula, whilst in some parts it is almost the sole radiation, producing strong photographic images where the eye sees nothing. The nebula G.C. 1180 surrounding the star *c* Orionis is scarcely visible on the N_1 and N_2 photograph, but it is a prominent feature on that obtained with the ultra-violet light, and is fairly bright on the Hβ plate.

This differential action suggests to Prof. Hartmann the presence of at least *three* gases in the Orion nebula, one of which emits the chief nebular radiations, the second hydrogen, and a third, which emits the radiation at λ 3727 (*Astrophysical Journal*, No. 5, vol. xxi.).

Periodicity of Aërolite Falls.—Among a number of interesting papers published by the Royal Astronomical Society of Canada ("Selected Papers and Proceedings," 1904) we notice one by Mr. W. H. S. Monck in which the author suggests that aërolites, like meteors, effect a certain periodicity. He first shows that the months of May and June stand out prominently in his catalogue of aërolites as the two months of the year in which a greater proportion of known falls have taken place. The number per diem for these two months is 1·34, whilst for the rest of the year it is only 0·81.

In an argument supporting the suggested periodical relation between various aërolite falls, Mr. Monck cites instances in which (1) aërolites fell within one or two days of each other in the same year; (2) aërolites fell on almost the same date in two consecutive years; (3) aërolites fell on nearly the same date after an interval of two or three years; and the number of cases quoted seems to place the matter beyond one of chance coincidences. Further, an analysis of the catalogue dates and numbers indicates a marked tendency for series of falls to congregate about certain dates, and for these falls Mr. Monck tentatively deduces periodicities varying from seven to twenty years.

The Reality of Supposed Changes on the Moon's Surface.—In a paper published in the June number of the *Bulletin de la Société astronomique de France* M. Puiseux discusses at some length the various observations of alleged changes on the lunar surface under the influence of the solar radiation. Going back to the earliest observations of details, he carefully considers each authoritative report of suspected change up to the most recent observations of the reported increase of the diameter of Linné during lunar eclipses. Summing up all the evidence thus examined, M. Puiseux arrives at the conclusion that the case for real changes taking place on the surface of our satellite is not established. He believes that the change of sensitiveness of the retina when observing faint objects is sufficient to account for the changes visually observed, whilst the different conditions of exposure when photographing the eclipsed moon might easily introduce the changes suspected from the examination of photographs.

The Circumzenithal Apparatus.—A new circumzenithal apparatus, devised by MM. Nušl and Frič for the determination of latitude, &c., was briefly described in these columns for August 20, 1903. A full and illustrated description of the instrument, and of the various improvements suggested by experience in its use, is now given in the Bulletin International of the Académie des Sciences de François Joseph I. (Prague, 1904) by the inventors, together with a detailed account of the observations already made and the methods employed in reducing the same.

THE NEEDS OF OUR OLDEST UNIVERSITY.

THE following statement has been drawn up by those professors and heads of departments of the University of Oxford whose names are appended, each being responsible for the details of his own and allied subjects, but expressing also a general sympathy with the scheme as a whole. It indicates the cost at which, in their opinion, all important existing deficiencies (except those of law) may be met by a generous provision for research as well as for teaching.

To carry out the scheme here set forth would require a capital outlay of about 564,000*l.*, and an annual income of about 93,000*l.*

A large proportion of the capital sum proposed for building the new laboratories, together with the whole sum proposed for the purchase of land near the museum, might be saved if the chemical and physical departments were moved from their present position. It is estimated that at a cost of about 60,000*l.* all existing or proposed departments in these branches of science could be accommodated, and space found for other proposed laboratories in the buildings thus set free.

With the sums hereafter named, in addition to her present resources, Oxford could successfully meet every pressing need as well as those demands which it is believed will pour in from many parts of the Empire, from the United States, and from Germany.

The present occasion has been thought a favourable one for stating clearly the full cost which, in the opinion of those who have signed this document, would enable Oxford confidently and hopefully to face the great responsibilities which have been placed upon her. But whatever be the outcome, her professors and heads of departments gladly welcome the inspiring opportunity for research and for education which these new responsibilities will assuredly bring. They will cheerfully attempt to meet the coming needs, even with the present inadequate resources, but they consider it right to point out that their work will be done under the greatest difficulties and therefore inadequately.

The insufficient endowment of many university departments and the necessity for further equipment have been subjects of anxious consideration for many years, culminating in the Vice-Chancellor's letter of February 20, 1902, to heads of institutions and departments—published with the answers in the "Statement of the Needs of the University" (Oxford, 1902). The estimates of expenditure given below have been largely based upon these published replies to a letter which was issued before our necessities became still more pressing in consequence of the will of Mr. Rhodes. Many additional needs not contemplated in the replies to the Vice-Chancellor have also come to light in the course of this inquiry, and are provided for in the following scheme. The published statement of needs is itself introduced by the following sentence (p. 3): "It is hardly necessary to add that in dealing with prospective needs it is generally impossible to form even an approximate estimate of the new and ever-increasing wants which the rapidly-growing requirements of our time may bring, and indeed in some instances (even since these statements were prepared) have already brought within view."

It has been assumed in the following statement that every important university chair, including all those to which the care of a department providing for one of the chief scientific subjects is attached, should be of the value of 900*l.* a year. In fixing this sum the traditions of the last Commission have been followed, but it is necessary to bear in mind that the growth of universities in the future and the competition between them may ultimately render such a sum insufficient to attract and retain the greatest workers and teachers. Under existing conditions we are convinced that it is adequate, but the university would require a large increase of income before she could provide for every important chair the stipend with which it is sometimes erroneously believed to be endowed.

Each new laboratory devoted to one of the principal branches of natural science has been estimated to cost 30,000*l.*, exclusive of site. It is believed that this sum would provide fittings and sufficient apparatus to begin teaching and research on an adequate scale, allowance being made for the material now in the possession of the university. It has been assumed that every important laboratory, both new and old, should receive an income of 3000*l.* a year, for professor's stipend, demonstrators, assistants, apparatus, and material for research and for teaching, and the general expenses of maintenance.

With such an income a professor could encourage several of his most promising men to do original work, giving them employment in teaching or working for the department during a part of their time.

Attention to the large and insistent needs of the existing and proposed scientific departments has been accompanied by a generous provision for the necessities of other subjects, and especially by the suggested increase of the Bodleian income to 23,000*l.* a year—even then less than one-third of the annual sum supplied to the National Library.

We feel that it is not too much to claim that the annual output in research and teaching from the small inadequately endowed—often miserably endowed—departments of the university, justifies the confident conclusion that a liberal provision for existing and imminent needs would be followed by results of the highest importance to the Empire as well as to the university. The results would be threefold—the advancement of learning, which is the highest and noblest function of a university; the adequate teaching of many subjects of the first importance, now imperfectly provided, or not provided at all; the inestimable benefits conferred upon students by living in an atmosphere of research.

H. B. Baker, F.R.S., Lee's reader in chemistry; Henry Balfour, curator of the Pitt-Rivers Museum; R. E. Baynes, Lee's reader in physics; T. K. Cheyne, Oriel professor of the interpretation of Holy Scripture; R. B. Clifton, F.R.S., professor of experimental philosophy; S. R. Driver, Regius professor of Hebrew; F. Y. Edgeworth, professor of political economy; E. B. Elliott, F.R.S., Waynflete professor of pure mathematics; Robinson Ellis, Corpus professor of Latin literature; W. Esson, F.R.S., Savilian professor of geometry; Arthur J. Evans, F.R.S., keeper of the Ashmolean Museum; C. H. Firth, Regius professor of modern history; P. Gardner, Lincoln and Merton professor of archæology; Francis Gotch, F.R.S., Waynflete professor of physiology; H. Goudy, Regius professor of civil law; F. Ll. Griffith, reader in Egyptology; W. Lock, Ireland professor of exegesis of Holy Scripture; A. E. H. Love, F.R.S., Sedleian professor of natural philosophy; R. W. Macan, university reader in ancient history; A. A. Macdonell, Boden professor of Sanskrit; D. S. Margoliouth, Laudian professor of Arabic; Henry A. Miers, F.R.S., professor of mineralogy; W. R. Morfill, professor of Russian; A. S. Napier, Merton professor of English language and literature; E. W. B. Nicholson, Bodley's librarian; W. Odling, F.R.S., Waynflete professor of chemistry; R. L. Ottley, Regius professor of pastoral theology; H. F. Pelham, Camden professor of ancient history; E. B. Poulton, F.R.S., Hope professor of zoology; Arthur Sidgwick, university reader in Greek; W. A. Raleigh, professor of English literature; John Rhys, Jesus professor of Celtic; James Ritchie, reader in pathology; W. Sanday, Margaret professor of divinity; A. H. Sayce, professor of Assyriology; Henry Sweet, university reader in phonetics; W. J. Sollas, F.R.S., professor of geology; John S. Townsend, F.R.S., Wykeham professor of physics; H. H. Turner, F.R.S., Savilian professor of astronomy; E. B. Tylor, F.R.S., professor of anthropology; Sydney H. Vines, F.R.S., Sherardian professor of botany; W. F. R. Weldon, F.R.S., Linacre professor of comparative anatomy; Joseph Wright, professor of comparative philology.

The late Regius professor of medicine, Sir John Burdon Sanderson, F.R.S., has expressed his approval.

Bodleian Library.—Fire-proofing, additional storage, additional reading-room, warming picture-gallery, electric lighting of camera (see also Central University Institution below, which it is suggested might liberate additional space for the Bodleian) (25,000*l.* : —); large increase of staff, filling up deficiencies in and maintaining special departments, printing the catalogue, binding (including arrears) (— : 13,000*l.*).

In this and all other cases the sum placed before the colon indicates capital outlay, that placed after the colon annual expenditure.

Central University Institution.—Containing workrooms and lecture-rooms for professors not otherwise provided for, university chest, delegates' rooms, committee rooms, &c.,

&c. The Clarendon building might be incorporated in Bodleian (cost, including site in a central position, 80,000*l.* :—); custody of same, warming, lighting, cleaning (— : 400*l.*); stipend of librarian for departmental libraries (— : 200*l.*).

Examination Schools.—Installation of the electric light (1000*l.* :—).

Theology.—Oriel professor of interpretation of Holy Scripture, stipend (the chair to be detached from the canonry at Rochester) (— : 900*l.*); Dean Ireland's professor, increase of stipend (— : 500*l.*); two additional professors, ecclesiastical history (— : 900*l.*), Christian archæology (— : 600*l.*); four additional readers (300*l.* each), ecclesiastical history, liturgiology, Rabbinical Hebrew, Biblical archæology (— : 1200*l.*); Grinfield lecturer on Biblical Greek, increase of stipend, making the lectureship equal to a readership, with reader's duties (— : 230*l.*); [additional readers (not exclusively concerned with theology)—Aramaic, Armenian, Coptic, Ethiopic] (— : 1200*l.*); travelling fellowships (2) (— : 400*l.*); capital fund from which payment might be made for occasional lectures (3000*l.* : —).

Greek, New Professor of Mediaeval and Modern Greek.—Stipend (— : 900*l.*).

Classical Palaeography.—Stipends of new readers, Greek and Latin (300*l.* each) (— : 600*l.*).

New chairs of Pali and Persian philology and literature (700*l.* each) (— : 1400*l.*).

Reader in Prakrit Philology and Literature.—Stipend (— : 300*l.*); increased stipend of 100*l.* to each of the five teachers of Indian vernacular, and additional grant to Indian Institute for purchase and care of Indian antiquities, &c. (300*l.*) (— : 800*l.*).

Ashmolean Museum.—Extension of site, increase of museum, cases and fittings, including a numismatic department and space for growth of the departments mentioned below (30,000*l.* : —); increased staff both for the museum and common service of the Ashmolean museum and university picture-gallery, and stipend of librarian (— : 1000*l.*); post-graduate studentship in archæology, art, &c. (— : 1000*l.*); purchase of specimens, books, &c. (— : 1500*l.*).

Classical Archaeology.—Increased stipend of chair, three new readerships (— : 1500*l.*).

Increase required for creation of new chairs of *Greek and Roman Epigraphy and Inscriptions* (700*l.* each), *Egyptology* (700*l.*), *Assyriology* (700*l.*), *History of Religions* (700*l.*), *Northern Archaeology* (900*l.*), *History of Architecture* (900*l.*) (— : 5300*l.*)

University Picture Gallery.—Extension of site, increase of gallery (10,000*l.* : —).

Slade Professor of Fine Art.—Increased stipend for resident chair, wages of attendant (— : 600*l.*); increase of stipends, purchases, &c. (— : 1000*l.*).

Pitt-Rivers Museum (Ethnology).—Increased space, building (8000*l.*), cases and fittings (4000*l.*), electric lighting (250*l.*), (12,250*l.* :—); increase of stipend, a professorship of anthropology might, at some future time, be combined with the curatorship (— : 700*l.*); assistants, service, general expenses and purchase of specimens (— : 700*l.*).

Astronomy, Savilian.—Building and apparatus (10,000*l.* : —); annual grant to make up a moderately efficient and well-equipped observatory with an income of 5000*l.* (— : 3500*l.*).

Increase required for creation of new chairs in scientific subjects and the building and new laboratories, &c. Under each chair the first-named sum represents capital expenditure for a new building, or for adapting an existing structure; the second sum represents the annual expenditure for the stipend of the chair, provision of demonstrators and assistants, the expenses of research and of service and maintenance:

Engineering (30,000*l.* : 3000*l.*); *Organic Chemistry* (30,000*l.* : 3000*l.*); *Physiological and Applied Botany* (20,000*l.* : 2000*l.*); *Biochemistry* (12,000*l* : 2000*l.*); *Experimental Psychology* (15,000*l.* : 2000*l.*); *Pathology* (— : 1500*l.*, allowing for existing readership); *Pharmacology and Materia Medica* (15,000*l.* : 1500*l.*, allowing for existing lectureship); *State Medicine and Hygiene* (10,000*l.* : 2000*l.*). The Regius professorship of medicine might perhaps be combined with one of the suggested new chairs of medicine.

Increase required for building new or adapting old laboratories and other capital expenditure, for existing chairs in scientific subjects, &c., for increase of the stipend of the chairs, for additional demonstrators and assistants, and for the expenses of research and of service and maintenance. The capital expenditure is placed first, the annual second, under each chair:

Experimental Philosophy, Clarendon.—*Light and Sound* (25,000*l.*, to include provision for elementary students and for examinations : 2000*l.*); *Electricity and Magnetism,* Wykeham (30,000*l.* : 2000*l.*); *Heat,* Lee's (30,000*l.* : 2000*l.*, allowing for Lee's readership); *Inorganic Chemistry,* Waynflete (30,000*l.*, old laboratory for extension of mineralogy, geology, and the Radcliffe library : 2200*l.*); *Physical Chemistry,* Lee's (30,000*l.* : 2000*l.*, allowing for Lee's readership); *Mineralogy,* Waynflete (15,000*l.* : 2200*l.*, including an assistant chair of metallurgy); *Geology* (20,000*l.* : 3000*l.*, including two assistant chairs); *Comparative Anatomy,* Linacre (— : 1000*l.*); *Zoology,* Hope (7000*l.*, chiefly for cabinets (— : 2500*l.*, including the maintenance of a tropical biological laboratory); *Systematic Botany,* Sherardian (— : 1000*l.*); *Animal Physiology,* Waynflete (6000*l.* : 1000*l.*); *Human Anatomy* (— : 1000*l.*).

Secretary of the Museum Delegates and of the Scientific Departments.—Increase of staff for the general purposes of the museum and to enable the secretary to collect all fees of the scientific departments (— : 400*l.*).

Sites for Scientific Departments.—For purchase of land in the neighbourhood of the present museum (50,000*l.* : —).

Geography.—Stipend of new chair (— : 700*l.*); assistant lecturers (— : 750*l.*).

University Chest.—Increased income to meet expenses in connection with additional buildings (— : 2000*l.*).

Modern History.—New chairs of economic history, colonial history, and military history (900*l.* each) (— : 2700*l.*); "seminars," maintenance and equipment of (100*l.* for each of the chairs) (— : 500*l.*); Lectureships—additional payment of existing lecturers and appointment of new lecturers, class expenses (— : 1500*l.*).

Political Economy.—Increased stipend of chair (200*l.*), see also the new chair of economic history proposed under Modern History; lecturers in economic theory, in statistics and applied economics, and in economic geography (200*l.* each); expenditure on examinations, &c. (50*l.*); secretary and clerk (150*l.*), (— : 1000*l.*).

English Language.—Two assistants in English language (— : 600*l.*).

English Literature.—Increased stipend of chair (400*l.*); two assistant lecturers in English literature (150*l.* each); one reader in rhetoric and criticism (300*l.*) (— : 1000*l.*).

Modern Languages.—Increase of stipends of Taylorian teachers to 600*l.* each (— : 1600*l.*); assistant lecturers (— : 1000*l.*).

New Chair of Phonetics.—Stipend (— : 900*l.*).

Total (546,250*l.* : 93,880*l.*).

PRELIMINARY REPORT OF THE DEPARTMENTAL COMMITTEE ON THE ROYAL COLLEGE OF SCIENCE AND ROYAL SCHOOL OF MINES.

TO THE MOST HONOURABLE THE MARQUESS OF LONDONDERRY, K.G., PRESIDENT OF THE BOARD OF EDUCATION.

MY LORD MARQUESS,

We, the Departmental Committee appointed by Your Lordship in April last to inquire into the present and future working of the Royal College of Science (including the Royal School of Mines), and into questions connected therewith, have the honour to submit a Preliminary Report.

I. In conducting the inquiry referred to us, we have held 17 meetings, at which we have examined 21 witnesses, the remainder of the time having been devoted to consideration of the information thus supplied to us. The evidence which we have received has been largely concerned with the history of the Royal College of Science (including the Royal School of Mines), with the character of the instruction now given therein, and with the possibility of attracting students more advanced in their education than the majority of those who now seek admission. On this branch of our inquiry we should be prepared to submit recommendations which we think would conduce

to increase the great usefulness of these institutions, even though conducted in the main upon their present lines; but we have thought it desirable to defer making such recommendations at the present time for reasons which we will now proceed to state.

II. It will be remembered that the terms of reference to the committee were as follows:—" To inquire into the present working of the Royal College of Science including the School of Mines: to consider in what manner the staff, together with the buildings and appliances now in occupation or in course of construction, may be utilised to the fullest extent for the promotion of higher scientific studies in connection with the work of existing or projected Institutions for instruction of the same character in the Metropolis or elsewhere: and to report on any changes which may be desirable in order to carry out such recommendations as they may make."

We recognise the admirable work accomplished by the Royal College of Science not only in training teachers, but in its general method of science teaching and in the promotion of research. Notwithstanding the marked increase in the number of institutions where teachers of science can be trained, the demand has also so increased that the need for teachers of science who have been well trained in scientific method is no less now than when the college was established as a normal school of science. At the same time it is agreed that there is an urgent national necessity for increased facilities for advanced instruction and research in science, especially in its application to industry. In view of this fact, and in view of certain munificent offers of aid towards the provision of such facilities in London, we have felt that it was necessary, in order to discharge the reference to us, to survey the resources available for, and the potentialities of, the principal existing and projected institutions of the character contemplated in our terms of reference. We have now proceeded far enough in this survey to satisfy ourselves that the moment is *primâ facie* opportune for a comprehensive scheme. The accomplishment, however, of such a scheme as we have in mind can only be brought about by the realisation of the offers of aid which are referred to above, and by the cooperation of certain influential bodies possessing an interest in such institutions as are dealt with in our proposals.

It has, therefore, become necessary for us to approach these bodies and the persons who have made these munificent offers. But before we proceed any further in this direction, we feel that our position would be strengthened if we could be assured that our proposals will meet with the approval of the Government, and we have accordingly decided, in view of the stage at which we have arrived, to present this preliminary report, in which we outline the scheme we think desirable, and specify the conditions which in our opinion would make it possible.

III. The conditions which, if fulfilled, would, in our opinion, ensure the success of the scheme are:—(1) The gift of a large capital sum (say not less than 100,000*l.*) for buildings and initial equipment.

(2) The gift of a considerable additional site (say not less than 4 acres) at South Kensington.

(3) The willingness of the Board of Education to allow their college at South Kensington to be brought into a scheme of common government and administration.

(4) The similar willingness of the City and Guilds of London Institute in respect of their college at South Kensington.

(5) The continuance of the Government contribution including the necessary provision for the maintenance of the new laboratories and other buildings of the Royal College of Science, now approaching completion.

(6) The continuance of the support given by the Corporation and Livery Companies of the City of London to the Central Technical College.

(7) The provision (in the proposed College of Applied Science at South Kensington) of instruction in certain departments of engineering either by new foundation or by transfer and enlargement of part of the work of some existing college or colleges (*e.g.* University College or King's College).

(8) The cooperation of the University of London.

(9) The assurance of a sufficient maintenance fund.[1]

IV. Given the fulfilment of the above conditions, we should be prepared to recommend such a scheme as is indicated in outline in the following paragraphs:—

(1) In considering the problem laid before us by the Government, we are impressed by the fact that the most urgent need in scientific education is the establishment of a centre in which the specialisation of the various branches of study and the equipment for the most advanced training and research should be such as ultimately to make it the chief technical school of the Empire.

So large a scheme cannot be carried out in a day, but we believe that the present is a favourable opportunity for making a beginning, and in the suggestions which follow we have kept the above end steadily in view. The existence of the Royal College of Science with the Royal School of Mines and of the Central Technical College in close proximity points to South Kensington as the best position for such a centre as we contemplate; and we have made careful inquiry as to the extent of the accommodation which is at present concentrated in that neighbourhood. It is as follows:—(*a*) Accommodation for about 200 students in the permanent part of the existing buildings of the Royal College of Science and the Royal School of Mines. (*b*) Accommodation for from 300 to 350 students including accommodation for work for about 100 advanced students in the physics and chemistry laboratories in the Royal College of Science, now approaching completion. (*c*) Accommodation for about 300 students in the existing buildings of the Central Technical College.

With the exception of the new laboratories of the Royal College of Science, these buildings are fully occupied by students, but the accommodation for mining and metallurgy is quite inadequate, and is to a great extent merely temporary. Further, the accommodation for engineering, whether in the Royal School of Mines or in the Central Technical College, is insufficient to meet the wants of many qualified students who are annually refused admission for want of space, and in no branch of applied science is sufficient provision made for advanced or specialised work.

There is no doubt that if arrangements could be made between the Government on the one hand and the City and Guilds of London Institute on the other, the resources of the above mentioned institutions could be used with far greater effect and economy.

(2) The buildings and equipment, even if such arrangement were made, though in many respects excellent and extensive, are quite inadequate for existing requirements, and still more for the purpose in view. The provision to be made for the future should include not only a fully developed School of Mining and Metallurgy and departments for the principal branches of engineering, but also for other special subjects.

We do not attempt in this Preliminary Report to draw up a detailed scheme, but the following principal subjects should be within the purview of the institution:—

As preparatory subjects—mathematics, physics, chemistry and geology. Under the general heading of civil engineering—works of construction, mechanical engineering, electrical engineering, mining engineering, marine engineering and naval architecture. Some branches of chemical technology, and certainly metallurgy.

As illustrations of the kind of higher or more specialised application of these subjects, some of which we suggest should be dealt with, we need only mention the applications of engineering to railway, dock, and hydraulic work; the development of electricity in the direction of electric traction, lighting and telegraphy, and electrochemistry. It would be impossible to provide for the whole of the above subjects at once. Some of the more specialised subjects, such as the advanced metallurgy of

[1] For such a maintenance fund we look to the following sources in addition to those mentioned above under headings 5 and 6.

(*a*) Any grant from the vote for university colleges to which the institution may be able to establish its claim.

(*b*) An annual grant from the London County Council.

(*c*) The Bessemer Memorial Fund (so far as not applied to capita expenditure).

(*d*) Fees of students.

(*e*) Endowment of special forms of instruction given by persons or bodies interested.

(*f*) Any portion of funds given for capital purposes which may remain available for income after the necessary capital expenditure.

iron and steel, and certain branches of manufacturing chemistry, would probably be better dealt with in institutions which are, or may be, established in the provinces. Even, however, if the scheme be restricted by the exclusion of such subjects, its realisation would require at least the whole of the site still available at South Kensington, and great advantage would be obtained by grouping the first extensions immediately round the nucleus provided by the Royal College of Science and Central Technical College.

We believe, however, that if the various London institutions concerned were willing to cooperate fully in the matter, and proper arrangements were made for coordination of the considerable resources already existing, the necessary special departments might be established early.

It is quite compatible with an effective realisation of the scheme that separate departments might be conducted in detached colleges.

In view of the terms of reference, we have given special consideration to the provision required for higher education in mining and metallurgy, and we are satisfied that the maintenance of a fully equipped Central School of Mines is desirable. While facilities for advanced instruction in coal mining and in the mining and metallurgy of iron are now available in some of the larger centres of those industries, it is important that there should be a central school affording a full course of instruction in the mining and metallurgy of metals produced in India and the Colonies, but not found, or not found in large quantity, within the United Kingdom. As London is the financial centre of many great engineering, mining, and metallurgical industries in the Colonies, it is in the opinion of several witnesses the best site for a more highly developed School of Mines which shall provide for the needs of the Empire. It has been proved to us that the number of Englishmen who rise to important posts in connection with the mining industries of India, Australia, and South Africa is less than is desirable.

We have, for the present, deferred consideration of the biological department of the Royal College of Science.

(3) We consider that the advantages of the higher technical courses, which we contemplate at South Kensington, should only be available for students who can pass a satisfactory test for admission thereto. The preliminary science and such rudiments of engineering as may be prescribed for candidates before entering on these higher courses might be obtained either in the laboratories of the Royal College of Science and Central Technical College, or elsewhere in London or the provinces. Admission to these higher courses should be restricted to duly qualified students who, it is hoped, would be attracted from all parts of the Empire.

(4) We think it is important that the interests both of pure and applied science should be adequately represented on the body which administers the new institution. It is of the first importance that there should be no divorce between teaching and research in technology on the one hand and in pure science on the other, and we therefore regard it as an advantage that ample provision has already been made by the Government for the teaching of certain sciences on a site which we hope may be connected even more closely than at present with the highest and most specialised branches of technology. With regard to both subjects, we believe that it may be necessary hereafter to limit the instruction to the higher branches of both pure and applied science.

(5) We do not contemplate that either the educational or financial administration of the Central College should be vested entirely in His Majesty's Government. Indeed, in the present case there is a special consideration which makes such an arrangement practically impossible. Our scheme, if carried into effect, will entail the hearty union and cooperation of several independent bodies in a common enterprise, and it would be an advantage to be able to accord to each cooperating institution an adequate share in the general control.

These considerations point to the creation of a council representing all the large interests concerned, including, of course, His Majesty's Government, who must always remain by far the chief supporters of the institution. We do not now enter into the details of an arrangement of the constitution of the council, as such details will largely depend on the success of negotiations which must await the decision of His Majesty's Government on the outlines of our proposals as now submitted.

Should the above proposals be accepted, it will follow that the State contribution to the institution will take the form of an annual grant in aid, the governing body retaining the power to carry over any balance remaining unexpended at the end of a year.

V. We feel that we should not be justified in inquiring whether the Board of Education would be willing to give their support to the foregoing scheme, depending as it does on the fulfilment of all or most of the conditions previously mentioned, unless we had taken steps to ascertain what prospect there is of their being fulfilled. We have good reason to believe that private munificence is prepared to provide a capital sum in excess of the minimum which we consider necessary to a successful issue, and that the Commissioners of the 1851 Exhibition are prepared, with their accustomed liberality where the advancement of higher education is concerned, to make available for a scheme, such as we have sketched, the additional site which will be required. We also confidently look for the cooperation of the University of London. Further, although public bodies or local authorities which contribute largely to the funds of the proposed institution may fairly ask for the reservation of some accommodation there for scholarship holders sent to it by themselves, yet it would appear that a considerably increased income would be available for the support of such an institution from the fees of fee-paying students. With this nucleus of additional resources thus provisionally secured, we feel justified in approaching the Board of Education. We accordingly desire to ask whether the Board are in a position to inform us (1) that, if it is found possible to establish a scheme such as we have sketched in outline, they will be willing to allow the Royal College of Science (including the Royal School of Mines) to be brought into it under a common government and administration; and (2) that the existing Government contribution to the support of these institutions will be continued under the new conditions on the scale already made necessary by the provision of the new laboratories of the Royal College of Science.

With such an assurance, and with such new resources as we have mentioned above, we feel that we could approach, with good prospect of success, other bodies whose cooperation we believe to be desirable, if not necessary, for the complete success of our proposals.

In conclusion, we desire to observe that absence of detail where it might have been looked for in certain portions of our proposals is not to be taken as meaning that we have not considered in some detail the ends which we wish to see attained. Our proposals at the present stage indicate only in outline what we have in view: how near an approach can be made to its attainment must depend on the resources which prove to be available, and cannot, therefore, from the nature of the case, be estimated with precision at the present time. Without, however, attempting now to exhaust the subject, we have submitted proposals framed in such a way as to suggest the establishment of an institution which will be pre-eminent in its combination of advanced teaching in certain branches of applied science, with instruction in pure science also developed to a very high standard.

We have the honour to be, My Lord Marquess, Your Lordship's obedient servants, R. B. Haldane, chairman, W. de W. Abney, E. H. Carbutt, W. S. Church, A. H. Leech, Philip Magnus, Walter McDermott, Francis Mowatt, F. G. Ogilvie, Reay, Arthur W. Rücker, Sidney Webb, J. Wernher, W. H. White, J. C. G. Sykes, secretary, F. E. Douglas, assistant secretary.

Letter from the Board of Education to the Secretary of the Departmental Committee on the Royal College of Science, &c.

BOARD OF EDUCATION, WHITEHALL, S.W., *April* 3, 1905.

Sir,

I am directed by the Board of Education to state that careful consideration has been given to the very valuable Preliminary Report of your Committee, dated February 20,

and I am to say that, while the point raised in subsection (2) of paragraph V. on page 5 of that Report cannot yet be definitely decided, the answer to subsection (1) in that paragraph is in the affirmative.

In sending this information, with the consent of His Majesty's Government, I am directed to express the warm appreciation of this Board for the great care with which this difficult subject has been thus far investigated by your Committee, and to say that the necessary discussions with His Majesty's Treasury upon the point involved in subsection (2) of paragraph V. will be completed with the least possible delay and, on a settlement being reached, information will be promptly sent to you as to these financial arrangements.

I have the honour to be, Sir, Your obedient Servant,

ROBERT L. MORANT, *Secretary of the Board of Education.*

Extract from the Speech of the Marquess of Londonderry, President of the Board of Education, at the Annual Dinner of the Institution of Mining and Metallurgy, May 10, 1905.

"I need not say that we have the hearty goodwill of the Treasury in endeavouring to carry out the recommendations of this strong Committee presided over by my friend, and I am able to tell you that, so far as the question of money—and, after all, money is the important question—is concerned, I have good grounds for believing that the Treasury, or rather the Chancellor of the Exchequer, has been very carefully considering the financial aspect of the new condition of things that will be brought about in regard to the Royal College of Science, if the changes I have hinted at actually take effect, and that he will see his way to make a reasonable increase in the sums at present devoted towards the expense of the Royal College of Science, so that the College, in its immensely enhanced possibilities of usefulness, owing to its large new buildings, may bring to the common aid, so to speak, not only its fabric and its excellent equipment, but also a satisfactory annual income, as a substantial contribution to what must be a heavy annual expenditure involved in the great work to be carried through."

NATIONAL LEAGUE FOR PHYSICAL IMPROVEMENT.

A MEETING, over which the Lord Mayor presided, was held at the Mansion House on June 28 for the purpose of establishing an association which for the time is described as a National League for Physical Education and Improvement, but the precise official title of which has not yet been decided. Among those present were the Bishop of Ripon, Sir Lauder and Lady Brunton, the Lord Chief Justice, Sir William Broadbent, Sir James Crichton Browne, Sir Norman and Lady Lockyer, Sir Henry Cunningham, Sir Henry Craik, Sir Benjamin Baker, Prof. Howard Marsh, and Sir Victor Horsley.

The chief objects of the association are to stimulate public interest in the physical condition of the people throughout the kingdom, to establish close association and centralisation of all societies and individuals trying to combat such influences as tend to produce national physical deterioration, to aid existing organisations, and to start organisations for physical health and well-being wherever none exists. As the purposes of the league are closely connected with medicine, it has been thought advisable to have it strongly backed by medical men before other classes of the community are asked to join, because most of them are less able to judge of its merits or demerits than medical men, and will consequently be led to decide their action in regard to it chiefly by the example of the leaders of the medical profession.

The council has published a draft scheme of the proposed association, according to which it would consist of territorial branches working in connection with a central body. It is suggested that each branch should see that instruction is furnished to the people on the laws of health generally, to mothers on the care of their own health and on the nurture and care of children, to girls on the methods of domestic and personal hygiene, and of cooking and housekeeping. Physical exercises and opportunity for open-air games should be obtained for both boys and girls; while the natural desire of young men to become volunteers should be encouraged, and marching drill, shooting practice, and all healthy sports fostered. A plan is outlined also for securing the cooperation of all persons in authority in different centres of population so that each section of the community may receive ultimately physical education of a suitable kind.

The following resolutions were adopted at the meeting:—

(1) That the causes which tend to impair the health of the nation, as disclosed by the report of the departmental committee, ought to be combated by united action. It is, therefore, recommended that all the agencies at present engaged in isolated work for that purpose should have the opportunity of combining, and thus cover the whole country.

(2) That this meeting assembled at the Mansion House, under the presidency of the Lord Mayor of London, therefore heartily approves of the federation designed for this purpose, and of the proposed effort to start organisations in those parts of the country where none exist.

In proposing the first resolution, the Bishop of Ripon said the result of the inter-departmental committee's report had been to point out that there are certain conditions at work which are not creditable to the civilised community. The report states that still-births ought to be registered, and that infantile mortality is very great; and that whereas during the last fifty years an improvement has taken place in the health of the people and in their dwellings, and the average length of life has been increased, it yet remains true that the percentage of infantile mortality has not decreased. The number of deaths in a year per thousand among children was 154 in the decade from 1851 to 1860, and the figure was the same in the decade 1891 to 1900. This shows that the benefits of the improved conditions go to the adult and not to the child. Conditions exist which must be remedied if the health of the population is to be sturdy, robust, and vigorous. The awakened interest in the question is largely due to the agencies which have been toiling to better the conditions and health of the people. If these agencies or societies and individuals have been able to achieve such admirable results by isolated effort, then by federation they could do a great deal more. The federation needs the cooperation of three great classes of public workers—the practical, the scientific, and the Parliamentary. A council would thus be formed of well digested and well considered thought as to the best means of helping forward every agency and initiating every kind of new enterprise which might contribute to the health, well-being, and physical stature, as well as to the moral greatness of the people of this country.

In seconding the resolution the Lord Chief Justice urged that innocent amusement and healthy education be provided throughout the country, through the municipal authorities, for a reasonable proportion of the lads and girls, so that their tastes may have an opportunity of being developed in a wholesome and healthy way.

THE UNIVERSITY COLLEGE OF SOUTH WALES.

THE Prince of Wales, in his capacity of Chancellor of the University of Wales, visited Cardiff on June 28 for the purposes of laying the foundation-stone of the new University College buildings in Cathays Park and of conferring a number of honorary degrees of the University of Wales.

The ceremony of laying the foundation-stone took place in the afternoon in the presence of a large and distinguished assembly. The president of the college, Sir Alfred Thomas, read an address of welcome to the Prince of Wales in which he outlined briefly the events which have led up to the possibility of the provision of buildings worthy of the educational work being accomplished by the University College of South Wales. The address stated that the Government in 1882 invited proposals from public

bodies for the location of the University College of South Wales and Monmouthshire. In their memorial the corporation of Cardiff promised that, in the event of Cardiff being selected, they would make adequate provision for the college.

The address continued:—"How they recognised their obligations is manifest by the noble site upon which we now stand. Your Royal Highness, by your presence here to-day, places the seal of your approval on the manner in which the corporation has redeemed the pledge which I, then as mayor, made in their name. We have had the good fortune to secure the services of an architect whose plans and designs have won the enthusiastic approval of educational experts. By the contributions of the people of South Wales and the splendid munificence of the Worshipful Drapers' Company, we are now in a position to build and maintain the arts, the administrative, and the research departments of the college. Our treasurer, to whom and to whose family we are so deeply indebted, trusts that this ceremony will prove such a stimulus to the patriotism of our people that the work now begun by Your Royal Highness will not cease until the whole scheme is completed."

During the course of his reply, the Prince of Wales remarked:—"As Chancellor of the University of Wales I am delighted to take part in this important ceremony and to lay the foundation-stone of the first block of what is hoped will some day grow into a building beautiful and dignified in design, complete and practical in its equipments. I congratulate you and all here present to-day in the proud fact that it is the liberality of the people of South Wales and Monmouthshire that makes it now possible to carry out a portion of the great scheme for the establishment in Cardiff of buildings worthy of their University College and worthy of the conception of its founders. I further note with great satisfaction that one of the largest of the London city companies has shown a practical sympathy in this great undertaking, and that the library buildings, one of the most important features in any college, will be the gift of the Worshipful Company of Drapers."

After referring to the fact that the site of the new buildings was formerly a monastic centre of learning, renowned at home and abroad, His Royal Highness continued:—"The new teaching and training differs in character from that which in the past rendered her colleges famous, for the Welsh people have determined that their university education shall be compatible with the modern wants of a new world. Its promoters and its authorities have recognised that this university should not exist merely for the purpose of the literary or the academic life, but should place itself in touch with and try to serve every form of intellectual activity, and to-day Cardiff is a constituent of the university, for under the charter the town council appoints two members of the university court, and by a standing ordinance of the town council the mayor is *ex officio* one of the members. So our university is by its constitution interwoven more closely perhaps than any other with the national life of the country; and this is no mere sentiment on the part of the people of Cardiff, for they have not only given this site for the college, but also presented to the university itself another site in this park and 6000*l.* for the erection of its registry."

The University College at Cardiff was founded in 1883 and incorporated in 1884, and is the largest of the three colleges constituting the University of Wales. It began with 150 students. In 1893 the number had increased to 347, and in 1903 to 647. Since its foundation the college has been housed in temporary quarters which used to be the premises of the Cardiff Infirmary. In 1895 the Government promised a grant of 20,000*l.* on condition that an equal amount was raised from private sources, and this was done. Then the Drapers' Company offered 10,000*l.*, which has subsequently been increased to 15,000*l.* The town gave the site, and altogether 132,000*l.* has been contributed. The total cost of the new buildings is estimated at 290,800*l.*, so that about 159,000*l.* is still required.

The conferring of degrees took place later in the day, and among the recipients of honours was Sir John Williams, upon whom the honorary D.Sc. was conferred.

THE LIÉGE MINING AND METALLURGICAL CONGRESS.

At the International Congress of Mining, Metallurgy, Mechanics, and Applied Geology held at Liége on June 25 to July 1, of which a brief report was published in Nature last week, numerous papers of great scientific interest were read.
